OpenMx Reference Manual

October 18, 2017

Date 2017-10-13
Title Extended Structural Equation Modelling
URL http://openmx.ssri.psu.edu, https://github.com/OpenMx/OpenMx
BugReports http://openmx.ssri.psu.edu/forums
Description Facilitates treatment of statistical model specifications as things that can be generated and manipulated programmatically.
Structural equation models may be specified with reticular action model matrices or paths, linear structural relations matrices or paths, or directly in matrix algebra.
Fit functions include full information maximum likelihood, maximum likelihood, and weighted least squares.
Example models include confirmatory factor, multiple group, mixture distribution, categorical threshold, modern test theory, differential equations, state space, and many others.

Convert a numeric or character vector into an optimizer status code

- **0, 'OK':** Optimization succeeded
- **1, 'OK/green':** Optimization succeeded, but the sequence of iterates has not yet converged. NPSOL was terminated because no further improvement could be made in the merit function (Mx status GREEN)
- **2, 'infeasible linear constraint':** The linear constraints and bounds could not be satisfied. The problem has no feasible solution.
- **3, 'infeasible non-linear constraint':** The nonlinear constraints and bounds could not be satisfied. The problem may have no feasible solution.
- **4, 'iteration limit':** The major iteration limit was reached (Mx status BLUE).
- **5, 'not convex':** The Hessian at the solution does not appear to be convex (Mx status RED).
- **6, 'nonzero gradient':** The model does not satisfy the first-order optimality conditions to the required accuracy, and no improved point for the merit function could be found during the final linesearch (Mx status RED)
- **7, 'bad deriv':** The function derivates returned by funcon or funobj seem incorrect.
- **9, 'internal error':** An input parameter was invalid
- **10, 'infeasible start':** Starting values were infeasible.

**Usage**

as.statusCode(code)
BaseCompute-class

Arguments

  code  a character or numeric vector of optimizer status code

See Also

  mxBootstrap summary.MxModel

Bollen

Description

  Data set used in some of OpenMx’s examples, for instance WLS. The data were reported in Bollen (1989, p. 428, Table 9.4) This set includes data from 75 developing countries each assessed on four measures of democracy measured twice (1960 and 1965), and three measures of industrialization measured once (1960).

Usage

  data("Bollen")

Format

  A data frame with 75 observations on the following 11 numeric variables.

    y1  Freedom of the press, 1960
    y2  Freedom of political opposition, 1960
    y3  Fairness of elections, 1960
    y4  Effectiveness of elected legislature, 1960
    y5  Freedom of the press, 1965
    y6  Freedom of political opposition, 1965
    y7  Fairness of elections, 1965
y8  Effectiveness of elected legislature, 1965
x1  GNP per capita, 1960
x2  Energy consumption per capita, 1960
x3  Percentage of labor force in industry, 1960

Details

Variables y1-y4 and y5-y8 are typically used as indicators of the latent trait of “political democracy” in 1960 and 1965 respectively. x1-x3 are used as indicators of industrialization (1960).

Source

The sem package (in turn, via pers. comm Bollen to Fox)

References

Examples

data(Bollen)
str(Bollen)
plot(y1 ~ y2, data = Bollen)

cvectorize Vectorize By Column

Description

This function returns the vectorization of an input matrix in a column by column traversal of the matrix. The output is returned as a column vector.

Usage

cvectorize(x)

Arguments

x           an input matrix.

See Also

rvectorize, vech, vechs
demoOneFactor

Examples

cvectorize(matrix(1:9, 3, 3))
cvectorize(matrix(1:12, 3, 4))

demoOneFactor  Demonstration data for a one factor model

Description

Data set used in some of OpenMx’s examples.

Usage

data("demoOneFactor")

Format

A data frame with 500 observations on the following 5 numeric variables.

x1
x2
x3
x4
x5

Details

Variables x1-x5 are typically used as indicators of the latent trait.

Source

Simulated.

References

The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.

Examples

data(demoOneFactor)
cov(demoOneFactor)
cor(demoOneFactor)
**demoTwoFactor**

*Demonstration data for a two factor model*

---

**Description**

Data set used in some of OpenMx’s examples.

**Usage**

```r
data("demoTwoFactor")
```

**Format**

A data frame with 500 observations on the following 10 numeric variables.

- x1
- x2
- x3
- x4
- x5
- y1
- y2
- y3
- y4
- y5

**Details**

Variables x1-x5 are typically used as indicators of one latent trait. Variables y1-y5 are typically used as indicators of another latent trait.

**Source**

Simulated.

**References**

The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.

**Examples**

```r
data(demoTwoFactor)
cov(demoTwoFactor)
cor(demoTwoFactor)
```
Description

Given an input matrix, diag2vec returns a column vector of the elements along the diagonal.

Usage

diag2vec(x)

Arguments

x an input matrix.

Details

Similar to the function diag, except that the input argument is always treated as a matrix (i.e., it doesn’t have diag()’s functions of returning an Identity matrix from an nrow specification, nor to return a matrix wrapped around a diagonal if provided with a vector). To get vector2matrix functionality, call vec2diag.

See Also

vec2diag

Examples

diag2vec(matrix(1:9, nrow=3))
# [,1]
# [1,] 1
# [2,] 5
# [3,] 9
diag2vec(matrix(1:12, nrow=3, ncol=4))

a12 a numeric vector
a13 a numeric vector
a14 a numeric vector
a15 a numeric vector
a16 a numeric vector
a17 a numeric vector
a18 a numeric vector

**Examples**

```r
data(dzmData)
str(dzmData)
```
**dzoData**  

**DZ opposite sex data**

---

**Description**

Data for extended twin example ETC88.R

**Usage**

```
data("dzoData")
```

**Format**

A data frame with 3981 observations on the following 37 variables.

- `famid` a numeric vector
- `e1` a numeric vector
- `e2` a numeric vector
- `e3` a numeric vector
- `e4` a numeric vector
- `e5` a numeric vector
- `e6` a numeric vector
- `e7` a numeric vector
- `e8` a numeric vector
- `e9` a numeric vector
- `e10` a numeric vector
- `e11` a numeric vector
- `e12` a numeric vector
- `e13` a numeric vector
- `e14` a numeric vector
- `e15` a numeric vector
- `e16` a numeric vector
- `e17` a numeric vector
- `e18` a numeric vector
- `a1` a numeric vector
- `a2` a numeric vector
- `a3` a numeric vector
- `a4` a numeric vector
- `a5` a numeric vector
- `a6` a numeric vector
Examples

data(dzoData)
str(dzoData)

Description

eigenval computes the real parts of the eigenvalues of a square matrix. eigenvec computes the real parts of the eigenvectors of a square matrix. ieigenval computes the imaginary parts of the eigenvalues of a square matrix. ieigenvec computes the imaginary parts of the eigenvectors of a square matrix. eigenval and ieigenval return nx1 matrices containing the real or imaginary parts of the eigenvalues, sorted in decreasing order of the modulus of the complex eigenvalue. For eigenvalues without an imaginary part, this is equivalent to sorting in decreasing order of the absolute value of the eigenvalue. (See Mod for more info.) eigenvec and ieigenvec return nxn matrices, where each column corresponds to an eigenvector. These are sorted in decreasing order of the modulus of their associated complex eigenvalue.

Usage

eigenval(x)
eigenvec(x)
ieigenval(x)
ieigenvec(x)

Arguments

x the square matrix whose eigenvalues/vectors are to be calculated.
example1

Details

Eigenvalues returned by eigenvec and ieigenvec are normalized to unit length.

See Also

eigen

Examples

A <- mxMatrix(values = runif(25), nrow = 5, ncol = 5, name = 'A')
G <- mxMatrix(values = c(0, -1, 1, -1), nrow=2, ncol=2, name='G')

model <- mxModel(A, G, name = 'model')

mxEval(eigenvec(A), model)
mxEval(eigenvec(G), model)
mxEval(eigenval(A), model)
mxEval(eigenval(G), model)
mxEval(ieigenvec(A), model)
mxEval(ieigenvec(G), model)
mxEval(ieigenval(A), model)
mxEval(ieigenval(G), model)

example1

Bivariate twin data example from Classic Mx Manual

Description

Data set used in some of OpenMx’s examples.

Usage

data("example1")

Format

A data frame with 400 observations on the following variables.

IDNum  Twin pair ID
Zygosity  Zygosity of the twin pair
X1  X variable for twin 1
Y1  Y variable for twin 1
X2  X variable for twin 2
Y2  Y variable for twin 2
Details

Same as example2 but in wide format instead of tall.

Source

Classic Mx Manual.

References

The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.

Examples

```r
data(example1)
plot(X2 ~ X1, data=example1)
```

---

example2  Bivariate twin data example from Classic Mx Manual

Description

Data set used in some of OpenMx’s examples.

Usage

```r
data("example2")
```

Format

A data frame with 800 observations on the following variables.

- **IDNum**  ID number
- **TwinNum**  Twin ID number
- **Zygosity**  Zygosity of the twin
- **X**  X variable for twins 1 and 2
- **Y**  Y variable for twins 1 and 2

Details

Same as example1 but in tall format instead of wide.

Source

Classic Mx Manual.

References

The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.
Examples

data(example2)
plot(Y ~ X, data=example2)

Description

Matrix exponential

Usage

expm(x)

Arguments

x matrix

factorExample1 Example Factor Analysis Data

Description

Data set used in some of OpenMx's examples.

Usage

data("factorExample1")

Format

A data frame with 500 observations on the following variables.

x1
x2
x3
x4
x5
x6
x7
x8
x9
Details

This appears to be a three factor model, but perhaps with an odd loading structure.

Source

Simulated

References

The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.

Examples

data(factorExample1)
round(cor(factorExample1), 2)

factanal(covmat=cov(factorExample1), factors=3, rotation="promax")

---

factorScaleExample1 Example Factor Analysis Data for Scaling the Model

Description

Data set used in some of OpenMx’s examples.

Usage

data("factorScaleExample1")

Format

A data frame with 200 observations on the following variables.

X1
X2
X3
X4
X5
X6
X7
X8
X9
X10
X11
X12
Details

This appears to be a three factor model with factor 1 loading on X1-X4, factor 2 on X5-X8, and factor 3 on X9-X12.

Source

Simulated

References

The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.

Examples

```r
data(factorScaleExample1)
round(cor(factorScaleExample1), 2)
```

---

factorScaleExample2   Example Factor Analysis Data for Scaling the Model

Description

Data set used in some of OpenMx’s examples.

Usage

```r
data("factorScaleExample2")
```

Format

A data frame with 200 observations on the following variables.

- X1
- X2
- X3
- X4
- X5
- X6
- X7
- X8
- X9
- X10
- X11
- X12
Details

This appears to be a three factor model with factor 1 loading on X1-X4, factor 2 on X5-X8, and factor 3 on X9-X12. It differs from factorScaleExample1 in the scaling of the variables.

Source

Simulated

References

The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.

Examples

```r
data(factorScaleExample2)
round(cor(factorScaleExample2), 2)

data(factorScaleExample2)
plot(sapply(factorScaleExample1, var), type='l', ylim=c(0, 6), lwd=3)
lines(1:12, sapply(factorScaleExample2, var), col='blue', lwd=3)
```

data(factorScaleExample2)
round(cor(factorScaleExample2), 2)

data(factorScaleExample2)
plot(sapply(factorScaleExample1, var), type='l', ylim=c(0, 6), lwd=3)
lines(1:12, sapply(factorScaleExample2, var), col='blue', lwd=3)

---

genericFitDependencies,MxBaseFitFunction-method

Add dependencies

Description

If there is an expectation, then the fit function should always depend on it. Hence, subclasses that implement this method must ignore the passed-in dependencies and use "dependencies <- callNextMethod()" instead.

Usage

```r
## S4 method for signature 'MxBaseFitFunction'
genericFitDependencies(.Object, flatModel, dependencies)
```

Arguments

- `.Object` fit function object
- `flatModel` flat model that lives with .Object
- `dependencies` accumulated dependency relationships
Holzinger and Swineford (1939) Ability data in 301 children from two schools

Description

This classic data set contains intelligence-test scores from 301 children on 26 distinct tests. The data are also available in the MBESS package.

The tests cover mental speed, memory, mathematical-ability, spatial, and verbal ability as listed below.

Usage

data("HS.ability.data")

Format

A data frame with 301 observations on the following 2 variables.

- id: student ID number (int)
- Gender: Sex (Factor w/ 2 levels “Female”, “Male”)
- grade: Grade in school (integer 7 or 8)
- agey: Age in years (integer)
- agem: Age in months (integer)
- school: School attended (Factor w/ 2 levels “Grant-White” and “Pasteur”) 
- addition: A speed test (numeric)
- code: A speed test (numeric)
- counting: A speed test (numeric)
- straight: A speed test (numeric)
- wordr: A memory subtest
- numberr: A memory subtest
- figurer: A memory subtest
- object: A memory subtest
- numberf: A memory subtest
- figurew: A memory subtest
- deduct: A mathematical subtest
- numeric: A mathematical subtest
- problemr: A mathematical subtest
- series: A mathematical subtest
- arithmet: A mathematical subtest
- visual: A spatial subtest
Details

The data are from children who differ in grade (seventh- and eighth-grade) and are nested in one of two schools (Pasteur and Grant-White). You will see it in use elsewhere, both in R (lavaan, MBESS), and in Joreskog (1969) reporting a cfa on the Grant-White school subject subset).

The last two tests are substitute versions for other tests. paperrev (a paper form board test) can substitute for paper and flagssub for the lozenges test flags.

Examples

data(HS.ability.data)
str(HS.ability.data)
levels(HS.ability.data$school)
plot(flags ~ flagssub, data = HS.ability.data)
**imxAddDependency**  
*Add a dependency*

**Description**

The dependency tracking system ensures that algebra and fit functions are not recomputed if their inputs have not changed. Dependency information is computed prior to handing the model off to the optimizer to reduce overhead during optimization.

**Usage**

```r
imxAddDependency(source, sink, dependencies)
```

**Arguments**

- `source`: a character vector of the names of the computation sources (inputs)
- `sink`: the name of the computation sink (output)
- `dependencies`: the dependency graph

**Details**

Each free parameter keeps track of all the objects that store that free parameter and the transitive closure of all algebras and fit functions that depend on that free parameter. Similarly, each definition variable keeps track of all the objects that store that free parameter and the transitive closure of all the algebras and fit functions that depend on that free parameter. At each iteration of the optimization, when the free parameter values are updated, all of the dependencies of that free parameter are marked as dirty (see `omxFitFunction.repopulateFun`). After an algebra or fit function is computed, `omxMarkClean()` is called to indicate that the algebra or fit function is updated. Similarly, when definition variables are populated in FIML, all of the dependencies of the definition variables are marked as dirty. Particularly for FIML, the fact that non-definition-variable dependencies remain clean is a big performance gain.

---

**imxAutoOptionValue**  
*imxAutoOptionValue*

**Description**

Convert "Auto" placeholders in global mxOptions to actual default values.

**Usage**

```r
imxAutoOptionValue(optionName, optionList = options()$mxOption)
```
imxCheckVariables

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>optionName</td>
<td>Character string naming the mxOption for which a numeric or integer value is wanted.</td>
</tr>
<tr>
<td>optionList</td>
<td>List of options; defaults to list of global mxOptions.</td>
</tr>
</tbody>
</table>

Details

This is an internal function exported for documentation purposes. Its primary purpose is to convert the on-load value of "Auto" to valid values for mxOptions ‘Gradient step size’, ‘Gradient iterations’, and ‘Function precision’—respectively, 1.0e-7, 1L, and 1e-14.

imxCheckMatrices

Description

This is an internal function exported for those people who know what they are doing.

Usage

imxCheckMatrices(model)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>model</td>
<td>model</td>
</tr>
</tbody>
</table>

imxCheckVariables

Description

This is an internal function exported for those people who know what they are doing.

Usage

imxCheckVariables(flatModel, namespace)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>flatModel</td>
<td>flatModel</td>
</tr>
<tr>
<td>namespace</td>
<td>namespace</td>
</tr>
</tbody>
</table>
**imxConDecMatrixSlots**  
*Condense/decondense slots of an MxMatrix*

**Description**
This is an internal function exported for those people who know what they are doing.

**Usage**
```r
imxConDecMatrixSlots(object)
```

**Arguments**
- **object** of class `MxMatrix`

**imxConstraintRelations**

**Description**
A string vector of valid constraint binary relations.

**Usage**
```r
imxConstraintRelations
```

**Format**
An object of class `character` of length 3.

**imxConvertIdentifier**

**Description**
This is an internal function exported for those people who know what they are doing.

**Usage**
```r
imxConvertIdentifier(identifiers, modelname, namespace, strict = FALSE)
```
Arguments

<table>
<thead>
<tr>
<th>identifiers</th>
<th>identifiers</th>
</tr>
</thead>
<tbody>
<tr>
<td>modelname</td>
<td>modelname</td>
</tr>
<tr>
<td>namespace</td>
<td>namespace</td>
</tr>
<tr>
<td>strict</td>
<td>strict</td>
</tr>
</tbody>
</table>

Description

This is an internal function exported for those people who know what they are doing.

Usage

```r
imxConvertLabel(label, modelname, dataname, namespace)
```

Arguments

<table>
<thead>
<tr>
<th>label</th>
<th>label</th>
</tr>
</thead>
<tbody>
<tr>
<td>modelname</td>
<td>modelname</td>
</tr>
<tr>
<td>dataname</td>
<td>dataname</td>
</tr>
<tr>
<td>namespace</td>
<td>namespace</td>
</tr>
</tbody>
</table>

Description

This is an internal function exported for those people who know what they are doing.

Usage

```r
imxConvertSubstitution(substitution, modelname, namespace)
```

Arguments

<table>
<thead>
<tr>
<th>substitution</th>
<th>substitution</th>
</tr>
</thead>
<tbody>
<tr>
<td>modelname</td>
<td>modelname</td>
</tr>
<tr>
<td>namespace</td>
<td>namespace</td>
</tr>
</tbody>
</table>
imxCreateMatrix  

Create a matrix

Description

This is an internal function exported for those people who know what they are doing.

Usage

    imxCreateMatrix(.Object, labels, values, free, lbound, ubound, nrow, ncol, 
                        byrow, name, condenseSlots, joinKey, joinModel)

Arguments

    .Object      the matrix
    labels       labels
    values       values
    free         free
    lbound       lbound
    ubound       ubound
    nrow         nrow
    ncol         ncol
    byrow        byrow
    name         name
    condenseSlots condenseSlots
    joinKey      joinKey
    joinModel    joinModel

imxDataTypes  Valid types of data that can be contained by MxData

Description

Valid types of data that can be contained by MxData

Usage

    imxDataTypes

Format

    An object of class character of length 5.
imxDefaultGetSlotDisplayNames

**Description**

Returns a list of display-friendly object slot names. This is an internal function exported for those people who know what they are doing.

**Usage**

```r
imxDefaultGetSlotDisplayNames(x, pattern = ".*")
```

**Arguments**

- `x`: The object from which to get slot names
- `pattern`: Initial pattern to match (default of ".*" matches any)

---

**imxDeparse**

*Deparse for MxObjects*

**Description**

Deparse for MxObjects

**Usage**

```r
imxDeparse(object, indent = " ")
```

**Arguments**

- `object`: object
- `indent`: indent
imxDependentModels  

**Description**

Are submodels dependence?

**Usage**

```r
imxDependentModels(model)
```

**Arguments**

- `model`  

---

imxDetermineDefaultOptimizer

**Description**

This is an internal function exported for those people who know what they are doing.

**Usage**

```r
imxDetermineDefaultOptimizer()
```

**Details**

Returns a character, the default optimizer

---

imxDiff  

**Description**

Set difference on regular types or S4 objects

**Usage**

```r
imxDiff(a, b, slots = c("setequal", "intersect"))
```

**Arguments**

- `a`  
- `b`  
- `slots`
**imxDmvnorm**  
* A C implementation of *dmvnorm*

**Description**
This API is visible to permit testing. Please do not use.

**Usage**
imxDmvnorm(loc, mean, sigma)

**Arguments**
- **loc**
- **mean**
- **sigma**

**imxEvalByName**  
* imxEvalByName*

**Description**
This is an internal function exported for those people who know what they are doing.

**Usage**
imxEvalByName(name, model, compute = FALSE, show = FALSE)

**Arguments**
- **name**
- **model**
- **compute**
- **show**

**Details**
This function should not be used in MxSummary. All summary information should be extracted from runstate.
**imxExtractMethod**

**Description**

This is an internal function exported for those people who know what they are doing.

**Usage**

`imxExtractMethod(model, index)`

**Arguments**

- `model` (model)
- `index` (index)

---

**imxExtractNames**

**Description**

This is an internal function exported for those people who know what they are doing.

**Usage**

`imxExtractNames(lst)`

**Arguments**

- `lst` (lst)

---

**imxExtractReferences**

**Description**

This is an internal function exported for those people who know what they are doing.

**Usage**

`imxExtractReferences(lst)`

**Arguments**

- `lst` (lst)
\section*{imxExtractSlot}

\textbf{Description}
Checks for and extracts a slot from the object. This is an internal function exported for those people who know what they are doing.

\textbf{Usage}
\begin{verbatim}
imxExtractSlot(x, name)
\end{verbatim}

\textbf{Arguments}
- \texttt{x} \hspace{1cm} The object
- \texttt{name} \hspace{1cm} the name of the slot

\section*{imxFlattenModel}

\textbf{Description}
Remove hierarchical structure from model.

\textbf{Usage}
\begin{verbatim}
imxFlattenModel(model, namespace)
\end{verbatim}

\textbf{Arguments}
- \texttt{model} \hspace{1cm} model
- \texttt{namespace} \hspace{1cm} namespace

\section*{imxFreezeModel}

\textbf{Description}
Remove free parameters and fit function from model.

\textbf{Usage}
\begin{verbatim}
imxFreezeModel(model)
\end{verbatim}

\textbf{Arguments}
- \texttt{model} \hspace{1cm} model
imxGenerateLabels

Description
This is an internal function exported for those people who know what they are doing.

Usage
imxGenerateLabels(model)

Arguments
model model

imxGenerateNamespace

Description
This is an internal function exported for those people who know what they are doing.

Usage
imxGenerateNamespace(model)

Arguments
model model

imxGenericModelBuilder

Description
This is an internal function exported for those people who know what they are doing.

Usage
imxGenericModelBuilder(model, lst, name, manifestVars, latentVars, submodels, remove, independent)
**Arguments**

- model
- lst
- name
- manifestVars
- latentVars
- submodels
- remove
- independent

**Description**

This is an internal function exported for those people who know what they are doing.

**Usage**

```r
imxGenSwift(tc, sites, sfile)
```

**Arguments**

- tc
- sites
- sfile

**Description**

Resize an MxMatrix while preserving entries

**Usage**

```r
imxGentleResize(matrix, dimnames)
```

**Arguments**

- matrix
- dimnames
**Value**

a resized MxMatrix

**Examples**

```r
m1 <- mxMatrix(values=1:9, nrow=3, ncol=3,
        dimnames=list(paste0('r',1:3), paste0('c',1:3)))
imxGentleResize(m1, dimnames=list(paste0('r',c(1,3,5)),
        paste0('c',c(2,4,6))))
```

**Description**

This is an internal function exported for those people who know what they are doing.

**Usage**

```r
imxGetNumThreads()
```

---

**imxGetSlotDisplayNames**

**Description**

Returns a list of display-friendly object slot names This is an internal function exported for those people who know what they are doing.

**Usage**

```r
imxGetSlotDisplayNames(object, pattern = ".*", slotList = slotNames(object),
        showDots = FALSE, showEmpty = FALSE)
```

**Arguments**

- **object**: The object from which to get slot names
- **pattern**: Initial pattern to match (default of ".*" matches any)
- **slotList**: List of slots for which to get display names (default = slotNames(object), i.e., all)
- **showDots**: Include slots whose names start with "." (default FALSE)
- **showEmpty**: Include slots with length-zero contents (default FALSE)
**imxHasConstraint**

**Description**

This is an internal function exported for those people who know what they are doing. This function checks if a model (or its submodels) has at least one MxConstraint.

**Usage**

```r
imxHasConstraint(model)
```

**Arguments**

- `model` model

---

**imxHasDefinitionVariable**

**Description**

This is an internal function exported for those people who know what they are doing. This function checks if a model (or its submodels) has at least one definition variable.

**Usage**

```r
imxHasDefinitionVariable(model)
```

**Arguments**

- `model` model

---

**imxHasNPSOL**

**Description**

`imxHasNPSOL`

**Usage**

```r
imxHasNPSOL()
```

**Value**

Returns TRUE if the NPSOL proprietary optimizer is compiled and linked with OpenMx. Otherwise FALSE.
imxHasOpenMP

Description
This is an internal function exported for those people who know what they are doing.

Usage
imxHasOpenMP()

imxIdentifier

Description
This is an internal function exported for those people who know what they are doing.

Usage
imxIdentifier(namespace, name)

Arguments
namespace
name

imxIndependentModels

Description
Are submodels independent?

Usage
imxIndependentModels(model)

Arguments
model
**imxInitModel**

**Description**

This is an internal function exported for those people who know what they are doing.

**Usage**

`imxInitModel(model)`

**Arguments**

- `model`  

---

**imxIsDefinitionVariable**

**Description**

This is an internal function exported for those people who know what they are doing.

**Usage**

`imxIsDefinitionVariable(name)`

**Arguments**

- `name`  

---

**imxIsPath**

**Description**

This is an internal function exported for those people who know what they are doing.

**Usage**

`imxIsPath(value)`

**Arguments**

- `value`
**imxJiggle**

---

**Description**

Jiggle parameter values, subject to box constraints. For internal use by mxTryHard(). This is an internal function exported for those people who know what they are doing.

**Usage**

`imxJiggle(params, lbounds, ubounds, dsn, loc, scale)`

**Arguments**

- `params` : Numeric vector of current free parameter values.
- `lbounds` : Numeric vector of lower bounds on parameters.
- `ubounds` : Numeric vector of upper bounds on parameters.
- `dsn` : Character string naming the family of distribution to be used.
- `loc` : Numeric vector of location parameters (medians).
- `scale` : Numeric vector of scale parameters (see source code).

---

**imxLocateFunction**

---

**Description**

This is an internal function exported for those people who know what they are doing.

**Usage**

`imxLocateFunction(function_name)`

**Arguments**

- `function_name` : function_name
Description
This is an internal function exported for those people who know what they are doing.

Usage
imxLocateIndex(model, name, referant)

Arguments
model    model
name     name
referant referant

Description
This is an internal function exported for those people who know what they are doing.

Usage
imxLocateLabel(label, model, parameter)

Arguments
label    label
model    model
parameter parameter
imxLog

Test thread-safe output code

Description
This is the code that the backend uses to write diagnostic information to standard error. This function should not be called from R. We make it available only for testing.

Usage
imxLog(str)

Arguments
str the character string to output

imxLookupSymbolTable

Description
This is an internal function exported for those people who know what they are doing.

Usage
imxLookupSymbolTable(name)

Arguments
name name

imxModelBuilder

Description
This is an internal function exported for those people who know what they are doing.

Usage
imxModelBuilder(model, lst, name, manifestVars, latentVars, submodels, remove, independent)
Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>model</td>
<td>model</td>
</tr>
<tr>
<td>lst</td>
<td>lst</td>
</tr>
<tr>
<td>name</td>
<td>name</td>
</tr>
<tr>
<td>manifestVars</td>
<td>manifestVars</td>
</tr>
<tr>
<td>latentVars</td>
<td>latentVars</td>
</tr>
<tr>
<td>submodels</td>
<td>submodels</td>
</tr>
<tr>
<td>remove</td>
<td>remove</td>
</tr>
<tr>
<td>independent</td>
<td>independent</td>
</tr>
</tbody>
</table>

Details

TODO: It probably makes sense to split this into separate methods. For example, modelAddVariables and modelRemoveVariables could be their own methods. This would reduce some cut&paste duplication.

Description

A list of supported model types

Usage

imxModelTypes

Format

An object of class list of length 3.

Description

This is an internal function exported for those people who know what they are doing.

Usage

imxMpiWrap(fun)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fun</td>
<td>fun</td>
</tr>
</tbody>
</table>
**imxOriginalMx**

**Description**

This is an internal function exported for those people who know what they are doing.

**Usage**

```r
imxOriginalMx(mx.filename, output.directory)
```

**Arguments**

- `mx.filename`
- `output.directory`

---

**imxPPML**

**Description**

Potentially enable the PPML optimization for the given model.

**Usage**

```r
imxPPML(model, flag = TRUE)
```

**Arguments**

- `model`  
  the MxModel to evaluate
- `flag`  
  whether to potentially enable PPML
Description

PPML can be applied to a number of special cases. This function will test the given model for all of these special cases.

Usage

```r
imxPPML.Test.Battery(model, verbose = FALSE, testMissingness = TRUE, testPermutations = TRUE, testEstimates = TRUE, testFakeLatents = TRUE, tolerances = c(0.001, 0.001, 0.001))
```

Arguments

- `model`: the model to test
- `verbose`: whether to print diagnostics
- `testMissingness`: try with missingness
- `testPermutations`: try with permutations
- `testEstimates`: examine estimates
- `testFakeLatents`: try with fake latents
- `tolerances`: a vector of tolerances

Details

Requirements for model passed to this function:
- Path-specified
- Means vector must be present
- Covariance data (with data means vector)
- (Recommended) All error variances should be specified on the diagonal of the S matrix, and not as a latent with a loading only on to that manifest

Function will test across all permutations of:
- Covariance vs Raw data
- Means vector present vs Means vector absent
- Path versus Matrix specification
- All orders of permutations of latents with manifests
Description

Test that PPML solutions match non-PPML solutions.

Usage

imxPPML.Test.Test(model, checkLL = TRUE, checkByName = FALSE, tolerance = 0.5, testEstimates = TRUE)

Arguments

model the MxModel to evaluate
checkLL whether to check log likelihood
checkByName check values using their names
tolerance closeness tolerance for check
testEstimates whether to test for the same parameter estimates

Details

This is an internal function used for comparing PPML and non-PPML solutions. Generally, non-developers will not use this function.

Description

This is an internal function exported for those people who know what they are doing.

Usage

imxPreprocessModel(model)

Arguments

model model
**imxReplaceMethod**

Description

This is an internal function exported for those people who know what they are doing.

Usage

imxReplaceMethod(x, name, value)

Arguments

x          the thing
name       name
value      value

**imxReplaceModels**

Description

Replace parts of a model

Usage

imxReplaceModels(model, replacements)

Arguments

model      model
replacements replacements
**imxReplaceSlot**

---

**Description**

Checks for and replaces a slot from the object. This is an internal function exported for those people who know what they are doing.

**Usage**

```r
imxReplaceSlot(x, name, value, check = TRUE)
```

**Arguments**

- `x` object
- `name` the name of the slot
- `value` replacement value
- `check` Check replacement value for validity (default TRUE)

---

**imxReportProgress**

---

**Description**

Prints a show status string to the console without emitting a newline.

**Usage**

```r
imxReportProgress(info, eraseLen)
```

**Arguments**

- `info` the character string to print
- `eraseLen` the number of characters to erase

**Examples**

```r
library(OpenMx)

previousLen <<- 0

easyReportProcess <- function(msg) {
  imxReportProgress(msg, previousLen)
  previousLen <<- nchar(msg)
}
```
demo <- function() {
  easyReportProcess("abc123")
  Sys.sleep(1)
  easyReportProcess("this is much longer")
  Sys.sleep(1)
  easyReportProcess("this is short")
  Sys.sleep(1)
  easyReportProcess("almost done")
  Sys.sleep(1)
  easyReportProcess(""")
  cat("DONE!", fill=TRUE)
}

## Not run: demo()

--

### Description

Vector of reserved names

### Usage

imxReservedNames

### Format

An object of class character of length 7.

--

### Description

This is an internal function exported for those people who know what they are doing.

### Usage

imxReverseIdentifier(model, name)

### Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>model</td>
<td>model</td>
</tr>
<tr>
<td>name</td>
<td>name</td>
</tr>
</tbody>
</table>
**imxRobustSE**

### Description

This is an internal function exported for those people who know what they are doing.

### Usage

```r
imxRobustSE(model, details = FALSE)
```

### Arguments

- **model**: An OpenMx model object that has been run
- **details**: logical. whether to return the full parameter covariance matrix

### Details

This function computes robust standard errors via a sandwich estimator. The "bread" of the sandwich is the numerically computed inverse Hessian of the likelihood function. This is what is typically used for standard errors throughout OpenMx. The "meat" of the sandwich is the covariance matrix of the numerically computed row derivatives of the likelihood function (i.e. row gradients). When `details=FALSE`, only the standard errors are returned. When `details=TRUE`, a list with named elements `SE` and `cov` is returned. The `SE` element is the vector of standard errors that is also returned when `details=FALSE`. The `cov` element is the full covariance matrix of the parameter estimates. The square root of the diagonal of `cov` gives the standard errors.

This function may not work correctly if `model` is a multigroup model. This function also does not correctly handle multilevel data.

---

**imxRowGradients**

### Description

This is an internal function exported for those people who know what they are doing.

### Usage

```r
imxRowGradients(model, robustSE = FALSE)
```

### Arguments

- **model**: An OpenMx model object that has been run
- **robustSE**: Logical; are the row gradients being requested to calculate robust standard errors?
Details

This function computes the gradient for each row of data. The returned object is a matrix with the same number of rows as the data, and the same number of columns as there are free parameters.

Description

This is an internal function exported for those people who know what they are doing.

Usage

`imxSameType(a, b)`

Arguments

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td></td>
</tr>
<tr>
<td>b</td>
<td></td>
</tr>
</tbody>
</table>

Description

The character between the model name and the named entity inside the model.

Usage

`imxSeparatorChar`

Format

An object of class `character` of length 1.
**imxSfClient**

**Description**
As of snowfall 1.84, the snowfall supervisor process stores an internal state information in a variable named ".sfOption" that is located in the "snowfall" namespace. The snowfall client processes store internal state information in a variable named ".sfOption" that is located in the global namespace.

**Usage**
imxSfClient()

**Details**
As long as the previous statement is true, then the current process is a snowfall client if-and-only-if exists("sfOption").

**imxSimpleRAMPredicate**

**Description**
This is an internal function exported for those people who know what they are doing.

**Usage**
imxSimpleRAMPredicate(model)

**Arguments**
model

**imxSparseInvert**

**Description**
This API is visible to permit testing. Please do not use.

**Usage**
imxSparseInvert(mat)

**Arguments**
mat the matrix to invert
### Description

This is an internal function exported for those people who know what they are doing.

### Usage

```r
imxSquareMatrix(.Object)
```

### Arguments

- `.Object` .Object

---

### Description

This is an internal function exported for those people who know what they are doing.

### Usage

```r
imxSymmetricMatrix(.Object)
```

### Arguments

- `.Object` .Object

---

### Description

This is an internal function exported for those people who know what they are doing.

### Usage

```r
imxTypeName(model)
```

### Arguments

- `model` model
Description
This is an internal function exported for those people who know what they are doing.

Usage
imxUntitledName()

Details
Returns a character, the name of the next untitled entity

imxUntitledNumber

Description
This is an internal function exported for those people who know what they are doing.

Usage
imxUntitledNumber()

Details
Increments the untitled number counter and returns its value

imxUntitledNumberReset

Description
This is an internal function exported for those people who know what they are doing.

Usage
imxUntitledNumberReset()

Details
Resets the imxUntitledNumber counter
imxUpdateModelValues  
imxUpdateModelValues

Description

Deprecated. This function does not handle parameters with equality constraints. Do not use.

Usage

imxUpdateModelValues(model, flatModel, values)

Arguments

model  model
flatModel  flat model
values  values to update

imxVariableTypes  imxVariableTypes

Description

This is an internal function exported for those people who know what they are doing.

Usage

imxVariableTypes

Format

An object of class character of length 2.

Details

The acceptable variable types
**imxVerifyMatrix**

### Description
This is an internal function exported for those people who know what they are doing.

### Usage

```r
imxVerifyMatrix(.Object)
```

### Arguments

- `.Object` .Object

**imxVerifyModel**

### Description
This is an internal function exported for those people who know what they are doing.

### Usage

```r
imxVerifyModel(model)
```

### Arguments

- `model` model

**imxVerifyName**

### Description
This is an internal function exported for those people who know what they are doing.

### Usage

```r
imxVerifyName(name, stackNumber)
```

### Arguments

- `name` name
- `stackNumber` stackNumber
imxVerifyReference

Description
This is an internal function exported for those people who know what they are doing.

Usage
imxVerifyReference(reference, stackNumber)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>reference</td>
<td>reference</td>
<td></td>
</tr>
<tr>
<td>stackNumber</td>
<td>stackNumber</td>
<td></td>

imxWlsChiSquare

Calculate Chi Square for a WLS Model

Description
This is an internal function used to calculate the Chi Square distributed fit statistic for weighted least squares models.

Usage
imxWlsChiSquare(model, J=NA)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>model</td>
<td>An MxModel object with acov (WLS) data</td>
<td></td>
</tr>
<tr>
<td>J</td>
<td>Optional pre-computed Jacobian matrix</td>
<td></td>
</tr>
</tbody>
</table>

Details
The Chi Square fit statistic for models fit with maximum likelihood depends on the difference in model fit in minus two log likelihood units between the saturated model and the more restricted model under investigation. For models fit with weighted least squares a different expression is required. If \( J \) is the first derivative (Jacobian) of the mapping from the free parameters to the unique elements of the expected covariance, means, and thresholds, \( J_c \) is the orthogonal complement of \( J \), \( W \) is the inverse of the full weight matrix, and \( e \) is the difference between the sample-estimated and model-implied covariance, means, and thresholds, then the Chi Square fit statistic is

\[
\chi^2 = e'J_c(WJ_c)^{-1}J'_ce
\]

with \( e' \) indicating the transpose of \( e \). This Equation 2.20a from Browne (1984) where he showed that this statistic is chi-square distributed with the conventional degrees of freedom.
Value

A named list with components

- **Chi** numeric value of the Chi Square fit statistic.
- **ChiDoF** degrees of freedom for the Chi Square fit statistic.

References

---

**imxWlsStandardErrors**  
*Calculate Standard Errors for a WLS Model*

Description

This is an internal function used to calculate standard errors for weighted least squares models.

Usage

`imxWlsStandardErrors(model)`

Arguments

- **model** An MxModel object with acov (WLS) data

Details

The standard errors for models fit with maximum likelihood are related to the second derivative (Hessian) of the likelihood function with respect to the free parameters. For models fit with weighted least squares a different expression is required. If \( J \) is the first derivative (Jacobian) of the mapping from the free parameters to the unique elements of the expected covariance, means, and thresholds, \( V \) is the weight matrix used, \( W \) is the inverse of the full weight matrix, and \( U = VJ(J'VJ)^{-1} \), then the asymptotic covariance matrix of the free parameters is

\[
A_{cov}(\theta) = U'WU
\]

with \( U' \) indicating the transpose of \( U \).

Value

A named list with components

- **SE** The standard errors of the free parameters
- **Cov** The full covariance matrix of the free parameters. The square root of the diagonal elements of Cov equals SE.
- **Jac** The Jacobian computed to obtain the standard errors.
References

---

jointdata  
*Joint Ordinal and continuous variables to be modeled together*

Description

Data set used in some of OpenMx’s examples.

Usage

data("jointdata")

Format

A data frame with 250 observations on the following variables.

- z1 Continuous variable
- z2 Ordinal variable with 2 levels (0, 1)
- z3 Continuous variable
- z4 Ordinal variable with 4 levels (0, 1, 2, 3)
- z5 Ordinal variable with 3 levels (0, 1, 3)

Details

Data generated to test the joint ML algorithm thoroughly.

Source

Simulated.

References

The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.

Examples

data(jointdata)
par(mfrow=c(2, 3))
h <- lapply(jointdata, hist)
par(mfrow=c(1, 1))
plot(z2 ~ z1, jointdata)
Example data for multiple regression among latent variables

Description

Data set used in some of OpenMx’s examples.

Usage

data("latentMultipleRegExample1")

Format

A data frame with 200 observations on the following variables.

X1  Factor 1 indicator
X2  Factor 1 indicator
X3  Factor 1 indicator
X4  Factor 1 indicator
X5  Factor 2 indicator
X6  Factor 2 indicator
X7  Factor 2 indicator
X8  Factor 2 indicator
X9  Factor 3 indicator
X10 Factor 3 indicator
X11 Factor 3 indicator
X12 Factor 3 indicator

Details

Factor 1 strongly predicts factor 3. Factor 2 weakly predicts factor 3.

Source

Simulated.

References

The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.

Examples

data(latentMultipleRegExample1)
round(cor(latentMultipleRegExample1), 2)
Example data for multiple regression among latent variables

Description
Data set used in some of OpenMx’s examples.

Usage
data("latentMultipleRegExample2")

Format
A data frame with 200 observations on the following variables.
X1  Factor 1 indicator
X2  Factor 1 indicator
X3  Factor 1 indicator
X4  Factor 1 indicator
X5  Factor 2 indicator
X6  Factor 2 indicator
X7  Factor 2 indicator
X8  Factor 2 indicator
X9  Factor 3 indicator
X10 Factor 3 indicator
X11 Factor 3 indicator
X12 Factor 3 indicator

Details
Factor 1 strongly predicts factor 3. Factor 2 weakly predicts factor 3. Very similar to latentMultipleRegExample1.

Source
Simulated.

References
The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.

Examples
data(latentMultipleRegExample2)
round(cor(latentMultipleRegExample2), 2)
Matrix logarithm

Description
Matrix logarithm

Usage
logm(x, tol = .Machine$double.eps)

Arguments
x matrix
tol tolerance

LongitudinalOverdispersedCounts
Longitudinal, Overdispersed Count Data

Description
Four-timepoint longitudinal data generated from an arbitrary Monte Carlo simulation, for 1000 simulees. The response variable is a discrete count variable. There are three time-invariant covariates. The data are available in both "wide" and "long" format.

Usage
data("LongitudinalOverdispersedCounts")

Format
The "long" format dataframe, longData, has 4000 rows and the following variables (columns):
1. id: Factor; simulee ID code.
2. time: Numeric; represents the time metric, wave of assessment.
3. x1: Numeric; time-invariant covariate.
4. x2: Numeric; time-invariant covariate.
5. x3: Numeric; time-invariant covariate.
6. y: Numeric; the response ("dependent") variable.

The "wide" format dataset, wideData, is a numeric 1000x12 matrix containing the following variables (columns):
1. id: Simulee ID code.
2. x1: Time-invariant covariate.
3. x3: Time-invariant covariate.
4. x3: Time-invariant covariate.
5. y0: Response at initial wave of assessment.
6. y1: Response at first follow-up.
7. y2: Response at second follow-up.
8. y3: Response at third follow-up.
9. t0: Time variable at initial wave of assessment (in this case, 0).
10. t1: Time variable at first follow-up (in this case, 1).
11. t2: Time variable at second follow-up (in this case, 2).
12. t3: Time variable at third follow-up (in this case, 3).

Examples

data(LongitudinalOverdispersedCounts)
head(wideData)
str(longData)

# Let's try ordinary least-squares (OLS) regression:
olsmod <- lm(y~tiem+x1+x2+x3, data=longData)
# We will see in the diagnostic plots that the residuals are poorly approximated by normality,
# and are heteroskedastic. We also know that the residuals are not independent of one another,
# because we have repeated-measures data:
plot(olsmod)
# In the summary, it looks like all of the regression coefficients are significantly different
# from zero, but we know that because the assumptions of OLS regression are violated that
# we should not trust its results:
summary(olsmod)

# Let's try a generalized linear model (GLM). We'll use the quasi-Poisson quasilikelihood
# function to see how well the y variable is approximated by a Poisson distribution
# (conditional on time and covariates):
glm.mod <- glm(y~tiem+x1+x2+x3, data=longData, family="quasipoisson")
# The estimate of the dispersion parameter should be about 1.0 if the data are
# conditionally Poisson. We can see that it is actually greater than 2,
# indicating overdispersion:
summary(glm.mod)

---

multiData1 Data for multiple regression

Description

Data set used in some of OpenMx's examples.

Usage

data("multiData1")
mxAlgebra

Format
A data frame with 500 observations on the following variables.

x1
x2
x3
x4
y

Details
x1-x4 are predictor variables, and y is the outcome.

Source
Simulated.

References
The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.

Examples

data(multiData1)
summary(lm(y ~ ., data=multiData1))
#results can be replicated in OpenMx.

mxAlgebra

Create MxAlgebra Object

Description
This function creates a new MxAlgebra object.

Usage
mxAlgebra(expression, name = NA, dimnames = NA, ..., fixed = FALSE,
joinKey=as.character(NA), joinModel=as.character(NA), verbose=0L)
**Arguments**

- **expression**: An R expression of OpenMx-supported matrix operators and matrix functions.
- **name**: An optional character string indicating the name of the object.
- **dimnames**: List. The dimnames attribute for the algebra: a list of length 2 giving the row and column names respectively. An empty list is treated as NULL, and a list of length one as row names. The list can be named, and the list names will be used as names for the dimensions.
- **fixed**: If TRUE, this algebra will not be recomputed automatically when things it depends on change. `mxComputeOnce` can be used to force it to recompute.
- **joinKey**: The name of the column in current model's raw data that is used as a foreign key to match against the primary key in joinModel's raw data.
- **joinModel**: The name of the model that this matrix joins against.
- **verbose**: For values greater than zero, enable runtime diagnostics.

**Details**

The `mxAlgebra` function is used to create algebraic expressions that operate on one or more MxMatrix objects. To evaluate an `MxAlgebra` object, it must be placed in an `MxModel` object, along with all referenced `MxMatrix` objects and the `mxFitFunctionAlgebra` function. The `mxFitFunctionAlgebra` function must reference by name the `MxAlgebra` object to be evaluated.

Note that, if the result for an `MxAlgebra` depends upon one or more "definition variables" (see `mxMatrix()`), then the value returned after the call to `mxRun()` will be computed using the values of those definition variables in the first (i.e., first before any automated sorting is done) row of the raw dataset.

The following operators and functions are supported in `mxAlgebra`:

**Operators**

- `solve()` Inversion
- `t()` Transposition
- `^` Elementwise powering
- `%^%` Kronecker powering
- `+` Addition
- `-` Subtraction
- `%*%` Matrix Multiplication
- `*` Elementwise product
- `/` Elementwise division
- `%%` Kronecker product
- `%%` Quadratic product: pre- and post-multiply B by A and its transpose t(A), i.e: `A %% B == A %*% B %*% t(A)`

**Functions**
cov2cor  Convert covariance matrix to correlation matrix
cho1   Cholesky Decomposition
cbind  Horizontal adhesion
rbind  Vertical adhesion
colSums Matrix column sums as a column vector
rowSums Matrix row sums as a column vector
det    Determinant
tr     Trace
sum    Sum
mean   Arithmetic mean
prod   Product
max    Maximum
min    Min
abs    Absolute value
sin    Sine
sinh   Hyperbolic sine
asin   Arcsine
asinh  Inverse hyperbolic sine
cos    Cosine
cosh   Hyperbolic cosine
acos   Arccosine
acosh  Inverse hyperbolic cosine
tan    Tangent
tanh   Hyperbolic tangent
atan   Arctangent
atanh  Inverse hyperbolic tangent
exp    Exponent
log    Natural Logarithm
mxRobustLog Robust natural logarithm
sqrt   Square root
p2z    Standard-normal quantile
logp2z Standard-normal quantile from log probabilities
lgamma Log-gamma function
lgamma1p Compute log(gamma(x+1)) accurately for small x

\texttt{eigenval}  Eigenvalues of a square matrix. Usage: eigenval(x); eigenvvec(x); ieigenval(x); ieigenvec(x)

\texttt{rvectorize}  Vectorize by row
mxAlgebra

cvectorize Vectorize by column
vech Half-vectorization
vechs Strict half-vectorization
vech2full Inverse half-vectorization
vechs2full Inverse strict half-vectorization
vec2diag Create matrix from a diagonal vector (similar to diag)
diag2vec Extract diagonal from matrix (similar to diag)
expm Matrix Exponential
logm Matrix Logarithm
omxExponential Matrix Exponential
omxMnor Multivariate Normal Integration
omxAllInt All cells Multivariate Normal Integration
omxNot Perform unary negation on a matrix
omxAnd Perform binary and on two matrices
omxOr Perform binary or on two matrices
omxGreaterThan Perform binary greater on two matrices
omxLessThan Perform binary less than on two matrices
omxApproxEquals Perform binary equals to (within a specified epsilon) on two matrices
omxSelectRows Filter rows from a matrix
omxSelectCols Filter columns from a matrix
omxSelectRowsAndCols Filter rows and columns from a matrix
mxEvaluateOnGrid Evaluate an algebra on an abscissa grid and collect column results

mxRobustLog is the same as log except that it returns -745 instead of -Inf for an argument of 0. The value -745 is less than log(4.94066e-324), a good approximation of negative infinity because the log of any number represented as a double will be of smaller absolute magnitude.

There are also several multiargument functions usable in MxAlgebras, which apply themselves elementwise to the matrix provided as their first argument. These functions have slightly different usage from their R counterparts. Their result is always a matrix with the same dimensions as that provided for their first argument. Values must be provided for ALL arguments of these functions, in order. Provide zeroes as logical values of FALSE, and non-zero numerical values as logical values of TRUE. For most of these functions, OpenMx cycles over values of arguments other than the first, by column (i.e., in column-major order), to the length of the first argument. Notable exceptions are the log, log.p, and lower.tail arguments to probability-distribution-related functions, for which only the [1,1] element is used. It is recommended that all arguments after the first be either (1) scalars, or (2) matrices with the same dimensions as the first argument.

<table>
<thead>
<tr>
<th>Function</th>
<th>Arguments</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>besselI &amp; besselK</td>
<td>x, nu, expon.scaled</td>
<td>Note that OpenMx does cycle over the elements of expon.scaled.</td>
</tr>
<tr>

<td>q, shape1, shape2, ncp, lower.tail, log.p</td>
<td>Values of ncp are handled as with dbeta().</td>
</tr>
</tbody>
</table>
mxAlgebra

dbinom x, size, prob, log

pbinom q, size, prob, lower.tail, log.p

dcauchy x, location, scale, log

pcauchy q, location, scale, lower.tail, log.p

dchisq x, df, ncp, log

pchisq q, df, ncp, lower.tail, log.p

The algorithm for the non-central chi-square distribution is used for non-negative values of ncp. Negative ncp values are ignored, and the algorithm for the central chi-square distribution is used.

omxDnbinom x, size, prob, mu, log

Exactly one of arguments size, prob, and mu should be negative, and therefore ignored. Otherwise, mu is ignored, possibly with a warning, and the values of size and prob are used, irrespective of whether they are in the parameter space. If only prob is negative, the algorithm for the alternative size-mu parameterization is used. If size is negative, a value for size is calculated as mu*prob/(1-prob), and the algorithm for the size-prob parameterization is used (note that this approach is ill-advised when prob is very close to 0 or 1).

omxPnbinom q, size, prob, mu, lower.tail, log.p

Arguments are handled as with omxDnbinom().

dpois x, lambda, log

ppois q, lambda, lower.tail, log.p

Value

Returns a new MxAlgebra object.

# [3,]  9  36  81

---

MxAlgebra-class  MxAlgebra Class

Description

MxAlgebra is an S4 class. An MxAlgebra object is a named entity. New instances of this class can be created using the function mxAlgebra.

Details

The MxAlgebra class has the following slots:

- name - The name of the object
- formula - The R expression to be evaluated
- result - a matrix with the computation result

The ‘name’ slot is the name of the MxAlgebra object. Use of MxAlgebra objects in the mxConstraint function or an objective function requires reference by name.

The ‘formula’ slot is an expression containing the expression to be evaluated. These objects are operated on or related to one another using one or more operations detailed in the mxAlgebra help file.

The ‘result’ slot is used to hold the results of computing the expression in the ‘formula’ slot. If the containing model has not been executed, then the ‘result’ slot will hold a 0 x 0 matrix. Otherwise the slot will store the computed value of the algebra using the final estimates of the free parameters.

Slots may be referenced with the $ symbol. See the documentation for Classes and the examples in the mxAlgebra document for more information.

References

The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.
MxAlgebraFormula-class

Description

This is an internal class for the formulas used in `mxAlgebra` calls.

mxAlgebraFromString

Create MxAlgebra object from a string

Description

Create MxAlgebra object from a string

Usage

`mxAlgebraFromString(algString, name = NA, dimnames = NA, ...)`

Arguments

- `algString` the character string to convert into an R expression
- `name` An optional character string indicating the name of the object.
- `dimnames` list. The dimnames attribute for the algebra: a list of length 2 giving the row and column names respectively. An empty list is treated as NULL, and a list of length one as row names. The list can be named, and the list names will be used as names for the dimensions.
- `...` Not used. Forces any remaining arguments to be specified by name.

Examples

```r
A <- mxMatrix(values = runif(25), nrow = 5, ncol = 5, name = 'A')
B <- mxMatrix(values = runif(25), nrow = 5, ncol = 5, name = 'B')
model <- mxModel(A, B, name = 'model',
                mxAlgebraFromString("A * (B + A)", name = 'test'))
model <- mxRun(model)
model[['test']]$result
A$values * (B$values + A$values)
```
mxAlgebraObjective  

DEPRECATED: Create MxAlgebraObjective Object

Description

WARNING: Objective functions have been deprecated as of OpenMx 2.0.

Please use MxFitFunctionAlgebra() instead. As a temporary workaround, MxAlgebraObjective returns a list containing a NULL MxExpectation object and an MxFitFunctionAlgebra object.

All occurrences of
mxAlgebraObjective(algebra, numObs = NA, numStats = NA)
Should be changed to
mxFitFunctionAlgebra(algebra, numObs = NA, numStats = NA)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>algebra</td>
<td>A character string indicating the name of an MxAlgebra or MxMatrix object to use for optimization.</td>
</tr>
<tr>
<td>numObs</td>
<td>(optional) An adjustment to the total number of observations in the model.</td>
</tr>
<tr>
<td>numStats</td>
<td>(optional) An adjustment to the total number of observed statistics in the model.</td>
</tr>
</tbody>
</table>

Details

NOTE: THIS DESCRIPTION IS DEPRECATED. Please change to using mxFitFunctionAlgebra as shown in the example below.

Fit functions are functions for which free parameter values are chosen such that the value of the objective function is minimized. While the other fit functions in OpenMx require an expectation function for the model, the mxAlgebraObjective function uses the referenced MxAlgebra or MxMatrix object as the function to be minimized.

If a model's primary objective function is a mxAlgebraObjective objective function, then the referenced algebra in the objective function must return a 1 x 1 matrix (when using OpenMx's default optimizer). There is no restriction on the dimensions of an objective function that is not the primary, or 'topmost', objective function.

To evaluate an algebra objective function, place the following objects in a MxModel object: a MxAlgebraObjective, MxAlgebra and MxMatrix entities referenced by the MxAlgebraObjective, and optional MxBounds and MxConstraint entities. This model may then be evaluated using the mxRun function. The results of the optimization may be obtained using the mxEval function on the name of the MxAlgebra, after the model has been run.

Value

Returns a list containing a NULL MxExpectation object and an MxFitFunctionAlgebra object. MxFitFunctionAlgebra objects should be included with models with referenced MxAlgebra and MxMatrix objects.
References

The OpenMx User's guide can be found at http://openmx.ssri.psu.edu/documentation.

See Also

mxAlgebra to create an algebra suitable as a reference function to be minimized. More information about the OpenMx package may be found here.

Examples

```r
# Create and fit a very simple model that adds two numbers using mxFitFunctionAlgebra

library(OpenMx)

# Create a matrix 'A' with no free parameters
A <- mxMatrix('Full', nrow = 1, ncol = 1, values = 1, name = 'A')

# Create an algebra 'B', which defines the expression A + A
B <- mxAlgebra(A + A, name = 'B')

# Define the objective function for algebra 'B'
objective <- mxFitFunctionAlgebra('B')

# Place the algebra, its associated matrix and its objective function in a model
tmpModel <- mxModel(model="Addition", A, B, objective)

# Evaluate the algebra
tmpModelOut <- mxRun(tmpModel)

# View the results
tmpModelOut$output$minimum
```

### mxAutoStart

Automatically set starting values for an MxModel

**Description**

Automatically set starting values for an MxModel

**Usage**

```r
mxAutoStart(model)
```

**Arguments**

- **model**
  The MxModel for which starting values are desired
Details

This function automatically picks very good starting values for many models (RAM, LISREL, Normal), including multiple group versions of these. It works for models with algebras. Models of continuous, ordinal, and joint ordinal-continuous variables are also acceptable. It works for models with covariance or raw data. However, it does not currently work for models with definition variables, state space models, and item factor analysis models.

The method used to obtain new starting values is quite simple. The user’s model is changed to an unweighted least squares (ULS) model. The ULS model is estimated and its final point estimates are returned as the new starting values.

Please note that ULS is sensitive to the scales of your variables. For example, if you have variables with means of 20 and variances of 0.001, then ULS will "weight" the means 20,000 times more than the variances and might result in zero variance estimates. Likewise if one variable has a variance of 20 and another has a variance of 0.001, the same problem may arise. To avoid this, make sure your variables are scaled accordingly. You could also use diagonally weighted least squares to obtain your own starting values.

Value

an MxModel with new free parameter values

Examples

# Use the frontpage model with negative variances to show better
# starting values
library(OpenMx)
data(demoOneFactor)

latents = c("G") # the latent factor
manifests = names(demoOneFactor) # manifest variables to be modeled

m1 <- mxModel("One Factor", type = "RAM",
manifestVars = manifests, latentVars = latents,
mxPath(from = latents, to = manifests),
mxPath(from = manifests, arrows = 2, values=-.2),
mxPath(from = latents, arrows = 2, free = FALSE, values = 1.0),
mxPath(from = "one", to = manifests),
mxData(demoOneFactor, type = "raw")
)

# Starting values imply negative variances!
mxGetExpected(m1, 'covariance')

# Use mxAutoStart to get much better starting values
m1s <- mxAutoStart(m1)
mxGetExpected(m1s, 'covariance')
mxAvailableOptimizers

Description

List the Optimizers available in this version, e.g. "SLSQP" "CSOLNP"

Usage

mxAvailableOptimizers()

Details

- note for advanced users: Special-purpose optimizers like Newton-Raphson or EM are not included in this list.

Value

- list of valid Optimizer names

See Also

- mxOption(model, "Default optimizer")

Examples

mxAvailableOptimizers()

MxBaseExpectation-class

MxBaseExpectation

Description

The virtual base class for all expectations. Expectations contain enough information to generate simulated data. This is an internal class and should not be used directly.

See Also

mxExpectationNormal, mxExpectationRAM, mxExpectationLISREL, mxExpectationStateSpace, mxExpectationBA81
MxBaseFitFunction-class

MxBaseFitFunction

Description

The virtual base class for all fit functions. This is an internal class and should not be used directly.

See Also

MxBaseNamed-class

MxBaseNamed

Description

This is an internal class and should not be used directly. It is the base class for named entities. Fit functions, expectations, and computes contain this class.

MxBaseObjectiveMetaData-class

MxBaseObjectiveMetaData

Description

This is an internal class and should not be used directly. It is the virtual base class for all objective functions meta-data.
mxBootstrap

Repeatedly estimate model using resampling with replacement

Description

Bootstrapping can help to assess the variability in parameter estimates. A new sample is draw from current data by uniformly sampling the original data with replacement. Then the model is fit to these new data. This process is repeated many times. Quantiles of the estimates from all these replications can be used to assess the variability of parameters.

Usage

mxBootstrap(model, replications=200, ...,
    data=NULL, plan=NULL, verbose=0L,
    parallel=TRUE, only=as.integer(NA),
    OK=mxOption(model, "Status OK"), checkHess=FALSE)

Arguments

- **model**: The MxModel to be run.
- **replications**: The number of resampling replications. If available, replications from prior mxBootstrap invocations will be reused.
- **...**: Not used. Forces remaining arguments to be specified by name.
- **data**: A character vector of data or model names
- **plan**: Deprecated
- **verbose**: For levels greater than 0, enables runtime diagnostics
- **parallel**: Whether to process the replications in parallel
- **only**: When provided, only the given replication from a prior run of mxBootstrap will be performed. See details.
- **OK**: The set of status code that are considered successful
- **checkHess**: Whether to approximate the Hessian in each replication

Details

By default, all datasets in the given model are resampled independently. If resampling is desired from only some of the datasets then the models containing them can be listed in the ‘data’ parameter.

When the model has a default compute plan and ‘checkHess’ is kept at FALSE then the Hessian will not be approximated or checked. On the other hand, ‘checkHess’ is TRUE then the Hessian will be approximated by finite differences. This procedure is of some value because it can be informative to check whether the Hessian is positive definite (see mxComputeHessianQuality). However, approximating the Hessian is often costly in terms of CPU time. For bootstrapping, the parameter estimates derived from the resampled data are typically of primary interest.
On occasion, replications will fail. Sometimes it can be helpful to exactly reproduce a failed replication to attempt to pinpoint the cause of failure. The ‘only’ option facilitates this kind of investigation. In normal operation, mxBootstrap uses the regular R random number generator to generate a seed for each replication. This seed is used to seed an internal pseudorandom number generator (currently the Mersenne Twister algorithm). These per-replication seeds are stored as part of the bootstrap output. When ‘only’ is specified, the associated stored seed is use to seed the internal random number generator so that identical weights can be regenerated.

‘mxBootstrap’ does not currently offer special support for nested or multilevel data. Rows are assumed model-wise independent.

**Value**

The given model is returned with the compute plan modified to consist of mxComputeBootstrap. Results of the bootstrap replications are stored inside the compute plan. mxSummary can be used to obtain per-parameter quantiles and standard errors.

**See Also**

mxBootstrapEval, mxComputeBootstrap, mxSummary, mxBootstrapStdizeRAMpaths, as.statusCode

**Examples**

```r
library(OpenMx)

data(multiData1)

manifests <- c("x1", "x2", "y")

biRegModelRaw <- mxModel(
  "Regression of y on x1 and x2",
  type="RAM",
  manifestVars=manifests,
  mxPath(from=c("x1","x2"), to="y",
    arrows=1,
    free=TRUE, values=.2, labels=c("b1", "b2")),
  mxPath(from=manifests,
    arrows=2,
    free=TRUE, values=.8,
    labels=c("VarX1", "VarX2", "VarE")),
  mxPath(from="x1", to="x2",
    arrows=2,
    free=TRUE, values=.2,
    labels=c("CovX1X2")),
  mxPath(from="one", to=manifests,
    arrows=1, free=TRUE, values=.1,
    labels=c("MeanX1", "MeanX2", "MeanY")),
  mxData(observed=multiData1, type="raw"))

biRegModelRawOut <- mxRun(biRegModelRaw)

boot <- mxBootstrap(biRegModelRawOut, 10)  # start with 10
```
summary(boot)

# Looks good, now do the rest
boot <- mxBootstrap(boot)
summary(boot)

# examine replication 3
boot3 <- mxBootstrap(boot, only=3)

print(coef(boot3))
print(boot$compute$output$raw[3,names(coef(boot3))])

---

mxBootstrapEval  Evaluate Values in a bootstrapped MxModel

Description

This function can be used to evaluate an arbitrary R expression that includes named entities from a MxModel object, or labels from a MxMatrix object.

Usage

mxBootstrapEval(expression, model, defvar.row = 1, ..., bq=c(.25,.75), method=c('bcbci','quantile'))

mxBootstrapEvalByName(name, model, defvar.row = 1, ..., bq=c(.25,.75), method=c('bcbci','quantile'))

omxBootstrapEval(expression, model, defvar.row = 1L, ...)

omxBootstrapEvalCov(expression, model, defvar.row = 1L, ...)

omxBootstrapEvalByName(name, model, defvar.row=1L, ...)

Arguments

expression  An arbitrary R expression.
name  The character name of an object to evaluate.
model  The model in which to evaluate the expression.
defvar.row  The row number for definition variables when compute=TRUE; defaults to 1. When compute=FALSE, values for definition variables are always taken from the first (i.e., first before any automated sorting is done) row of the raw data.
...  Not used. Forces remaining arguments to be specified by name.
bq  numeric. A vector of quantiles to be used to summarize bootstrap replication.
method  character. One of ‘quantile’ or ‘bcbci’.
mxBootstrapEval

Details

The argument ‘expression’ is an arbitrary R expression. Any named entities that are used within the R expression are translated into their current value from the model. Any labels from the matrices within the model are translated into their current value from the model. Finally the expression is evaluated and the result is returned. To enable debugging, the ‘show’ argument has been provided. The most common mistake when using this function is to include named entities in the model that are identical to R function names. For example, if a model contains a named entity named ‘c’, then the following mxEval call will return an error: mxEval(c(A, B, C), model).

The mxEvalByName function is a wrapper around mxEval that takes a character instead of an R expression.

The default behavior is to use the ‘bcbci’ method, due to its superior theoretical properties. However, its bias-correction can lead to nonsensical results if the number of bootstrap replications is too small for the desired coverage probability. For example, a lower confidence limit of -Inf, or an upper confidence limit smaller than the point estimate, are signals that more replications are needed.

Value

omxBootstrapEval and omxBootstrapEvalByName return the raw matrix of cvectorize’d results. omxBootstrapEvalCov returns the covariance matrix of the cvectorize’d results. mxBootstrapEval and mxBootstrapEvalByName return the cvectorize’d results summarized by method at quantiles bq.

Examples

library(OpenMx)

testModel <- mxModel(  
  model="testModel",  
  mxData(data.frame(weight=1.0, value=1:10), "raw", weight = "weight"),  
  mxMatrix("Full", nrow = 1, ncol = 1, values = 1, free=TRUE, name = "A"),  
  mxAlgebra(data.weight * filteredDataRow, name = 'rowAlgebra'),  
  mxAlgebra((sum(rowResults) - A)^2, name = 'reduceAlgebra'),  
  mxFitFunctionRow('rowAlgebra', 'reduceAlgebra', 'value'))

testModel <- mxRun(testModel)
testBoot <- mxBootstrap(testModel)
summary(testBoot)

mxBootstrapEval(A^2, testBoot)
**mxBootstrapStdizeRAMpaths**

*Bootstrap distribution of standardized RAM path coefficients*

**Description**

Uses the bootstrap distribution of a RAM model’s free parameters to produce a bootstrap distribution of standardized path coefficients. Model must have already been run through `mxBootstrap()`.

**Usage**

```r
mxBootstrapStdizeRAMpaths(model, bq=c(.25,.75),
method=c('bcbci','quantile'), returnRaw=FALSE)
```

**Arguments**

- `model`: An MxModel that uses RAM expectation and has already been run through `mxBootstrap()`.
- `bq`: Quantiles corresponding to the lower and upper limits, respectively, of the bootstrap confidence interval.
- `method`: Character string. One of 'bcbci' or 'quantile'.
- `returnRaw`: Logical; should the function return the raw bootstrapping results? Defaults to `FALSE`, in which case a dataframe summarizing the results is returned.

**Details**

In effect, what `mxBootstrapStdizeRAMpaths()` does is use the point estimates from each bootstrap replication to produce `mxStandardizeRAMpaths()` output for each replication. The output of `mxStandardizeRAMpaths()` has one entry for each nonzero path coefficient. Therefore, it is possible (though unlikely) that the number of nonzero paths, or which elements of the A and S RAM matrices are nonzero, may vary among bootstrap replications. Such an occurrence defies simple summary of the standardized paths’ bootstrapping results. In this case, a raw list of bootstrapping results is returned, with a warning, if `returnRaw=TRUE`, or an error is throw if `returnRaw=FALSE`. `mxBootstrapStdizeRAMpaths()` ignores any submodels of `model`. That is, it must be able to find, in the MxModel it is provided, a RAM expectation and an MxComputeBootstrap object. It can be run on submodels directly.

**Value**

Under extraordinary circumstances described above, `mxBootstrapStdizeRAMpaths()` may return a list object. In ordinary circumstances, if `returnRaw=FALSE` (default), it returns a dataframe containing, *inter alia*, the standardized path coefficients as estimated from the real data, their bootstrap SEs, and the lower and upper limits of a bootstrap confidence interval. If instead `returnRaw=TRUE`, `mxBootstrapStdizeRAMpaths()` returns a matrix containing the raw bootstrap results; this matrix has one column per nonzero path coefficient, and one row for each successfully converged bootstrap replication.

Examples

```r
require(OpenMx)
data(myFADataRaw)
myFADataRaw <- myFADataRaw[,c("x1","x2","x3","x4","x5","x6")]
dataRaw <- mxData( observed=myFADataRaw, type="raw" )
resVars <- mxPath( from=c("x1","x2","x3","x4","x5","x6"), arrows=2,
                  free=TRUE, values=c(1,1,1,1,1,1),
                  labels=c("e1","e2","e3","e4","e5","e6")
 )
latVar <- mxPath( from="F1", arrows=2,
                  free=TRUE, values=1, labels="varF1" )
facLoads <- mxPath( from="F1", to=c("x1","x2","x3","x4","x5","x6"), arrows=1,
                    free=c(TRUE,TRUE,TRUE,TRUE,TRUE,TRUE), values=c(1,1,1,1,1,1),
                    labels=c("l1","l2","l3","l4","l5","l6")
 )
means <- mxPath( from="one", to=c("x1","x2","x3","x4","x5","x6","F1"), arrows=1,
                 free=c(TRUE,TRUE,TRUE,TRUE,TRUE,TRUE,FALSE),
                 values=c(1,1,1,1,1,1,0),
                 labels=c("meanx1","meanx2","meanx3","meanx4","meanx5","meanx6",NA) )
oneFactorModel <- mxModel("Common Factor Model Path Specification", type="RAM",
                         manifestVars=c("x1","x2","x3","x4","x5","x6"), latentVars="F1",
                         dataRaw, resVars, latVar, facLoads, means)
oneFactorFit <- mxRun(oneFactorModel)
set.seed(170505)
# replications=20 is only here to make the example run quickly.
# You should use many more replications for higher accuracy.
oneFactorBoot <- mxBootstrap(oneFactorFit, replications=20)
mxBootstrapStdizeRAMpaths(oneFactorBoot)
```

---

### mxBounds

#### Create MxBounds Object

**Description**

This function creates a new `MxBounds` object.

**Usage**

```r
mxBounds(parameters, min = NA, max = NA)
```

**Arguments**

- **parameters**: A character vector indicating the names of the parameters on which to apply bounds.
MxBounds-class

min - A numeric value for the lower bound. NA means use default value.
max - A numeric value for the upper bound. NA means use default value.

Details

Creates a set of boundaries or limits for a parameter or set of parameters. Parameters may be any free parameter or parameters from an MxMatrix object. Parameters may be referenced either by name or by referring to their position in the 'spec' matrix of an MxMatrix object.

Minima and maxima may be specified as scalar numeric values.

Value

Returns a new MxBounds object. If used as an argument in an MxModel object, the parameters referenced in the 'parameters' argument must also be included prior to optimization.

References

The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.

MxBounds for the S4 class created by mxBounds. MxMatrix and mxMatrix for free parameter specification. More information about the OpenMx package may be found here.

Examples

#Create lower and upper bounds for parameters 'A' and 'B'
bounds <- mxBounds(c('A', 'B'), 3, 5)

#Create a lower bound of zero for a set of variance parameters
varianceBounds <- mxBounds(c('Var1', 'Var2', 'Var3'), 0)

MxBounds-class

MxBounds Class

Description

MxBounds is an S4 class. New instances of this class can be created using the function mxBounds.

Details

The MxBounds class has the following slots:

min - The lower bound
max - The upper bound
parameters - The vector of parameter names
The 'min' and 'max' slots hold scalar numeric values for the lower and upper bounds on the list of parameters, respectively.

Parameters may be any free parameter or parameters from an MxMatrix object. Parameters may be referenced either by name or by referring to their position in the 'spec' matrix of an MxMatrix object. To affect an estimation or optimization, an MxBounds object must be included in an MxModel object with all referenced MxAlgebra and MxMatrix objects.

Slots may be referenced with the $ symbol. See the documentation for Classes and the examples in the mxBounds document for more information.

References

The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.

See Also

mxBounds for the function that creates MxBounds objects. MxMatrix and mxMatrix for free parameter specification. More information about the OpenMx package may be found here.
mxCheckIdentification  

Check that a model is locally identified

Description
Use the dimension of the null space of the Jacobian to determine whether or not a model is identified local to its current parameter values. The output is a list of the the identification status, the Jacobian, and which parameters are not identified.

Usage
mxCheckIdentification(model, details=TRUE)

Arguments
- **model**: A MxModel object or list of MxModel objects.
- **details**: logical.

Details
The mxCheckIdentification function is used to check that a model is identified. That is, the function will tell you if the model has a unique solution in parameter space. The function is most useful when applied to either (a) a model that has been run and had some NA standard errors, or (b) a model that has not been run but has reasonable starting values. In the former situation, mxCheckIdentification is used as a diagnostic after a problem was indicated. In the latter situation, mxCheckIdentification is used as a sanity check.

The method uses the Jacobian of the model expected means and the unique elements of the expected covariance matrix with respect to the free parameters. It is the first derivative of the mapping between the free parameters and the sufficient statistics for the Normal distribution. The method does not depend on data, but does depend on the current values of the free parameters. Thus, it only provides local identification, not global identification. Because the method does not depend on data, the model still could be empirically unidentified due to missing data.

The Jacobian is evaluated numerically and generally takes a few seconds, but much less than a minute.

The identification may not be accurate for model where definition variables are used. Currently, only the first row of the definition variable is evaluated.

When TRUE, the 'details' argument provides the names of the non-identified parameters. Otherwise, only the status and Jacobian are returned.

Value
A named list with components
- **status**: logical. TRUE if the model is locally identified; otherwise FALSE.
- **jacobian**: matrix. The numerically evaluated Jacobian.
- **non_identified_parameters**: vector. The free parameter names that are not identified.

)
fit2 <- mxRun(model2)

id2 <- mxCheckIdentification(fit2)
id2$status
# The model is locally identified

# Build a model from the solution of the previous one
# but now the factor variance is also free
model2n <- mxModel(fit2, name="Non Identified Two Factor",
  mxPath(from=latents[1], arrows=2, free=TRUE, values=1)
)

mid2 <- mxCheckIdentification(model2n)
mid2$non_identified_parameters
# The factor loadings and factor variance
# are not identified.
```

**Description**

This function creates a new MxCI object, which are used to estimate likelihood-based confidence intervals.

**Usage**

```r
mxCI(reference, interval = 0.95, type = c("both", "lower", "upper"), ..., boundAdj=TRUE)
```

**Arguments**

- `reference`: A character vector of free parameters, mxMatrices, mxMatrix elements and mx-Algebras on which confidence intervals are to be estimated, listed by name.
- `interval`: A scalar numeric value indicating the confidence interval to be estimated. Must be between 0 and 1. Defaults to 0.95.
- `type`: A character string indicating whether the upper, lower or both confidence limits are returned. Defaults to "both".
- `...`: Not used. Forces remaining arguments to be specified by name.
- `boundAdj`: Whether to correct the likelihood-based confidence intervals for a lower or upper bound.

**Details**

The mxCI function creates MxCI objects, which can be used as arguments in MxModel objects. When models containing MxCI objects are optimized using mxRun with the ‘intervals’ argument set to TRUE, likelihood-based confidence intervals are returned. The likelihood-based confidence intervals calculated by MxCI objects are symmetric with respect to the change in likelihood in either direction, and are not necessarily symmetric around the parameter estimate. Estimation of confidence intervals requires both that an MxCI object be included in the model and that the ‘intervals’ argument of the mxRun function is set to TRUE. When estimated, confidence intervals can be accessed in the model output at `$output$confidenceIntervals` or by using summary on a fitted MxModel object.

A typical use case is when a model includes non-linear constraints, and hence, standard errors are not available. In all cases, a two-sided hypothesis test is assumed. Therefore, the upper bound will exclude 2.5% (for interval=0.95) even though only one bound is requested. To obtain a one-sided CI for a one-sided hypothesis test, interval=0.90 will obtain a 95% confidence interval.

When a confidence interval is requested for a free parameter (not an algebra) constrained by a lower bound or an upper bound (but not both) and boundAdj=TRUE then the Wu & Neale (2012) correction is used. This improves the accuracy of the confidence interval when the parameter is estimated close to the bound. For example, this correction will be activated when a variance with a lower bound of $10^{-6}$ and no upper bound that is estimated close to the bound. The sample size, or more precisely effective sample size for that particular parameter, will determine how close the variance needs to be to the bound at $10^{-6}$ to activate the correction.

The likelihood-based confidence intervals returned using MxCI are obtained by increasing or decreasing the value of each parameter until the -2 log likelihood of the model increases by an amount corresponding to the requested interval. The confidence limit specified by the ‘interval’ argument is transformed into a corresponding difference in the model -2 log likelihood based on the likelihood
ratio test. Thus, a requested confidence interval for a parameter will first determine the corresponding quantile from the chi-squared distribution with one degree of freedom (a value of 3.841459 when a 95 percent confidence interval is requested). That quantile will be populated into either the ‘lowerdelta’ slot, the ‘upperdelta’ slot, or both in the output MxCI object.

Estimation of likelihood-based confidence intervals begins after optimization has been completed, with each parameter moved in the direction(s) specified in the ‘type’ argument until the specified increase in -2 log likelihood is reached. All other free parameters are left free for this stage of optimization. This process repeats until all confidence intervals have been calculated. The calculation of likelihood-based confidence intervals can be computationally intensive, and may add a significant amount of time to model estimation when many confidence intervals are requested.

Multiple parameters, MxMatrices and MxAlgebras may be listed in the ‘reference’ argument. Individual elements of MxMatrices and MxAlgebras may be listed as well, using the syntax “matrix[row,col]” (see Extract for more information). Only scalar numeric values for the ‘interval’ argument are supported. Users requesting different confidence ranges for different parameters must use separate mxCI statements. MxModel objects can hold multiple MxCI objects, but only one confidence interval may be requested per named-entity.

Confidence interval estimation may result in model non-convergence at the confidence limit. Separate optimizer messages may be passed for each confidence limit. This has no impact on the parameter estimates themselves, but may indicate a problem with the referenced confidence limit. Model non-convergence for a particular confidence limit may indicate parameter interdependence or the influence of a parameter boundary.

These error messages and their meanings are listed in the help for mxSummary.

The validity of a confidence limit can be checked by running a model with the appropriate parameter fixed at the confidence limit in question. If the confidence limit is valid, the -2 log likelihoods of these two models should differ by the specified chi-squared criterion (as set using the ‘lowerdelta’ or ‘upperdelta’ slots in the MxCI object (you can choose which of these to set via the type parameter of mxCI).

Value

Returns a new MxCI object. If used as an argument in an MxModel object, the parameters, MxMatrices and MxAlgebras listed in the ‘reference’ argument must also be included prior to optimization.

`MxCI` for the S4 class created by `mxCI`. `mxComputeConfidenceInterval` is the internal compute plan that implements the algorithm. `MxMatrix` and `mxMatrix` for free parameter specification. More information about the OpenMx package may be found here.

Examples

```r
library(OpenMx)

# generate data
covariance <- matrix(c(1.0, 0.5, 0.5, 1.0),
nrow=2,
dimnames=list(c("a", "b"), c("a", "b")))
data <- mxData(covariance, "cov", numObs=100)

# create an expected covariance matrix
expect <- mxMatrix("Symm", 2, 2,
  free=TRUE,
  values=c(1, .5, 1),
  labels=c("var1", "cov12", "var2"),
  name="expectedCov")

# request 95 percent confidence intervals
ci <- mxCI(c("var1", "cov12", "var2"))

# specify the model
model <- mxModel(model="Confidence Interval Example",
data, expect, ci,
  mxExpectationNormal("expectedCov", dimnames=c("a", "b")),
  mxFitFunctionML())

# run the model
results <- mxRun(model, intervals=TRUE)

# view confidence intervals
print(summary(results)$CI)

# view all results
summary(results)

# remove a specific mxCI from a model
model <- mxModel(model, remove=TRUE, model$intervals[['cov12']])
model$intervals

# remove all mxCI from a model
model <- mxModel(model, remove=TRUE, model$intervals)
model$intervals
```
MxCI-class

Description
MxCI is an S4 class. An MxCI object is a named entity. New instances of this class can be created using the function `mxCI`. MxCI objects may be used as arguments in the `mxModel` function.

Details
The MxCI class has the following slots:

- reference - The name of the object
- lowerdelta - Either a matrix or a data frame
- upperdelta - A vector for means, or NA if missing

The reference slot contains a character vector of named free parameters, `MxMatrices` and `MxAlgebras` on which confidence intervals are desired. Individual elements of `MxMatrices` and `MxAlgebras` may be listed as well, using the syntax “matrix[row,col]" (see `Extract` for more information).

The lowerdelta and upperdelta slots give the changes in likelihoods used to define the confidence interval. The upper bound of the likelihood-based confidence interval is estimated by increasing the parameter estimate, leaving all other parameters free, until the model -2 log likelihood increased by `upperdelta`. The lower bound of the confidence interval is estimated by decreasing the parameter estimate, leaving all other parameters free, until the model -2 log likelihood increased by `lowerdata`.

Likelihood-based confidence intervals may be specified by including one or more MxCI objects in an `MxModel` object. Estimation of confidence intervals requires model optimization using the `mxRun` function with the ‘intervals’ argument set to TRUE. The calculation of likelihood-based confidence intervals can be computationally intensive, and may add a significant amount of time to model estimation when many confidence intervals are requested.

mxCompare

**Likelihood ratio test**

**Description**

Compare the fit of a model or set of models to a reference model or set of reference models.

**Usage**

```r
mxCompare(base, comparison, ..., all = FALSE,
           boot=FALSE, replications=400, previousRun=NULL, checkHess=FALSE)
mxCompareMatrix(models, statistic, ..., 
                 boot=FALSE, replications=400, previousRun=NULL, checkHess=FALSE)
```

**Arguments**

- `base` A MxModel object or list of MxModel objects.
- `comparison` A MxModel object or list of MxModel objects.
- `models` A MxModel object or list of MxModel objects.
- `statistic` A vector of up to two statistics with which to populate the returned matrix.
- `all` A boolean value on whether to compare all bases with all comparisons. Defaults to FALSE.
- `boot` Whether to use the bootstrap distribution to compute the p-value.
- `replications` How many replications to use to approximate the bootstrap distribution.
- `previousRun` Results to re-use from a previous bootstrap.
- `checkHess` Whether to approximate the Hessian in each replication

**Details**

The `mxCompare` function is used to compare the fit of one or more `MxMatrix` objects with output to one or more comparison models. `mxCompareMatrix` compares all the models provided against each other. Fit statistics for the comparison model or models are subtracted from the fit statistics for the base model or models. All models included in the ‘base’ argument are also listed without comparison (compared to a <NA> model) to present their raw fit statistics.

Model comparisons are made by subtracting the fit of the comparison model from the fit of a base model. To make sure that the differences between models are positive and yield p-values for likelihood ratio tests, the model or models listed in the ‘base’ argument should be more saturated (i.e., more estimated parameters and fewer degrees of freedom) than models listed in the ‘comparison’ argument. For `mxCompareMatrix` only the comparisons that make sense will be included. If a comparison is made where the comparison model has a higher minus 2 log likelihood (-2LL) than the base model, then the difference in their -2LLs will be negative. P-values for likelihood ratio tests will not be reported when either the -2LL or degrees of freedom for the comparison are negative.
When multiple models are included in both the ‘base’ and ‘comparison’ arguments, comparisons are made between the two lists of models based on the value of the ‘all’ argument. If ‘all’ is set to FALSE (default), then the first model in the ‘base’ list is compared to the first model in the ‘comparison’ list, second with second, and so on. If there are an unequal number of ‘base’ and ‘comparison’ models, then the shorter list of models is repeated to match the length of the longer list. For example, comparing base models ‘B1’ and ‘B2’ with comparison models ‘C1’, ‘C2’ and ‘C3’ will yield three comparisons: ‘B1’ with ‘C1’, ‘B2’ with ‘C2’, and ‘B1’ with ‘C3’. Each of those comparisons are prefaced by a comparison between the base model and a missing comparison model to present the fit of the base model.

If ‘all’ is set to TRUE, all possible comparisons between base and comparison models are made, and one entry is made for each base model. All comparisons involving the first model in ‘base’ are made first, followed by all comparisons with the second ‘base’ model, and so on. When there are multiple models in either the ‘base’ or ‘comparison’ arguments but not both, then the ‘all’ argument does not affect the set of comparisons made.

The following columns appear in the output:

- **base**: Name of the base model.
- **comparison**: Name of the comparison model. Is <NA> for the first.
- **ep**: Estimated parameters of the comparison model.
- **minus2LL**: Minus 2*log-likelihood of the comparison model. If the comparison model is <NA>, then the minus 2*log-likelihood of the base model is given.
- **df**: Degrees in freedom of the comparison model. If the comparison model is <NA>, then the degrees of freedom of the base model is given.
- **AIC**: Akaike’s Information Criterion for the comparison model. If the comparison model is <NA>, then the AIC of the base model is given.
- **diffLL**: Difference in minus 2*log-likelihoods of the base and comparison models. Will be positive when base model -2LL is higher than comparison model -2LL.
- **diffdf**: Difference in degrees of freedoms of the base and comparison models. Will be positive when base model DF is lower than comparison model DF (base model estimated parameters is higher than comparison model estimated parameters).
- **p**: P-value for likelihood ratio test based on diffLL and diffdf values.

The mxCompare function will give a p-value for any comparison in which both ‘diffLL’ and ‘diffdf’ are non-negative. However, this p-value is based on the assumptions of the likelihood ratio test, specifically that the two models being compared are nested. The likelihood ratio test and associated p-values are not valid when the comparison model is not nested in the referenced base model. For a more accurate p-value, the empirical bootstrap distribution can be computed (‘boot=TRUE’). However, ‘replications’ must be set high enough for an accurate approximation. The Monte Carlo SE of a proportion for B replications is \( \sqrt{\frac{p \cdot (1 - p)}{B}} \), but this will be zero if p is zero, which is nonsense. Note that a parametric-bootstrap p-value of zero must be interpreted as \( p < \frac{1}{B} \), which, depending on B and the desired Type I error rate, may not be "statistically significant."

When ‘boot=TRUE’, the model has a default compute plan, and ‘checkHess’ is kept at FALSE then the Hessian will not be approximated or checked. On the other hand, ‘checkHess’ is TRUE then the Hessian will be approximated by finite differences. This procedure is of some value because it can be informative to check whether the Hessian is positive definite (see mxComputeHessianQuality).
However, approximating the Hessian is often costly in terms of CPU time. For bootstrapping, the parameter estimates derived from the resampled data are typically of primary interest.

Use `options('digits' = N)` to set the minimum number of significant digits to be printed in values. The `mxCompare` function does not directly accept a `digits` argument, and depends on the value of the `digits` option.

**See Also**

- `mxModel`: `options` (use `options('mxOptions')` to see all the OpenMx-specific options)

**Examples**

```r
# data and model objects

data(demoOneFactor)
manifests <- names(demoOneFactor)
latents <- c("G1")
model1 <- mxModel(model="One Factor", type="RAM",
  manifestVars = manifests,
  latentVars = latents,
  mxPath(from = latents, to=manifests),
  mxPath(from = manifests, arrows = 2),
  mxPath(from = latents, arrows = 2, free = FALSE, values = 1.0),
  mxData(cov(demoOneFactor), type = "cov", numObs = 500)
)

fit1 <- mxRun(model1)

latents <- c("G1", "G2")
model2 <- mxModel(model="Two Factor", type="RAM",
  manifestVars = manifests,
  latentVars = latents,
  mxPath(from = latents[1], to=manifests[1:3]),
  mxPath(from = latents[2], to=manifests[4:5]),
  mxPath(from = manifests, arrows = 2),
  mxPath(from = latents, arrows = 2, free = FALSE, values = 1.0),
  mxData(cov(demoOneFactor), type = "cov", numObs=500)
)

fit2 <- mxRun(model2)

mxCompare(fit1, fit2)

# vary precision of the output
oldPrecision = as.numeric(options("digits"))
options("digits" = 1)
mxCompare(fit1, fit2)
options("digits" = oldPrecision)
```
Description

This is an internal class and should not be used directly.

mxComputeBootstrap

Repeatedly estimate model using resampling with replacement

Description

This is a low-level compute plan object to perform resampling with replacement.

Usage

mxComputeBootstrap(data, plan, replications=200, ..., verbose=0L, parallel=TRUE, freeSet=NA_character_, OK=c("OK", "OK/green"), only=NA_integer_)

Arguments

data A vector of dataset or model names.
plan The compute plan used to optimize the model for each data set.
replications The number of resampling replications. If available, replications from prior mxBootstrap invocations will be reused.
... Not used. Forces remaining arguments to be specified by name.
verbose For levels greater than 0, enables runtime diagnostics
parallel Whether to process the replications in parallel
freeSet names of matrices containing free variables
OK The set of status code that are considered successful
only When provided, only the given replication from a prior run of mxBootstrap will be performed. See details.

Details

The 'only' option facilitates investigation of a single replication attempt.
Value

Output is stored in the compute object’s output slot. Specifically, `model$compute$output$raw` contains a data frame with parameters in columns and replications in rows. In addition to parameters, the seed, fit, and statusCode of the replication is also included.

When ‘only’ is set to a particular replications, the weight vectors (one per dataset) are also returned in the compute object’s output slot. `model$compute$output$weight` is a character vector (by dataset name) of numeric vectors (the weights). These weights can be used to recreate a model identical to the model used in the given replication.

See Also

`mxBootstrap`, `as.statusCode`
mxComputeEM

Fit a model using DLR's (1977) Expectation-Maximization (EM) algorithm

Usage

mxComputeEM(expectation = NULL, predict = NA_character_, mstep, observedFit = "fitfunction", ..., maxIter = 500L, tolerance = 1e-09, verbose = 0L, freeSet = NA_character_, accel = "varadhan2008", information = NA_character_, infoArgs = list(), estep = NULL)

References

Arguments

- **expectation**: a vector of expectation names (DEPRECATED)
- **predict**: what to predict from the observed data (DEPRECATED)
- **mstep**: a compute plan to optimize the completed data model
- **observedFit**: the name of the observed data fit function (defaults to "fitfunction")
- **maxIter**: maximum number of iterations
- **tolerance**: optimization is considered converged when the maximum relative change in fit is less than tolerance
- **verbose**: level of diagnostic output
- **freeSet**: names of matrices containing free variables
- **accel**: name of acceleration method ("varadhan2008" or "ramsay1975")
- **information**: name of information matrix approximation method
- **infoArgs**: arguments to control the information matrix method
- **estep**: a compute plan to perform the expectation step

Details

This compute plan does not work with any and all expectations. It requires a special kind of expectation that can predict its missing data to create a completed data model.

The EM algorithm does not produce a parameter covariance matrix for standard errors. The Oakes (1999) direct method and S-EM, an implementation of Meng & Rubin (1991), are included. Ramsay (1975) was recommended in Bock, Gibbons, & Muraki (1988).

mxComputeGenerateData  
*Generate data*

**Description**
Generate data specified by the model expectations.

**Usage**
```
mxComputeGenerateData(expectation = "expectation")
```

**Arguments**
- `expectation`: a character vector of expectations to generate data for

mxComputeGradientDescent

*Optimize parameters using a gradient descent optimizer*

**Description**
This optimizer does not require analytic derivatives of the fit function. The fully open-source CRAN version of OpenMx offers 2 choices, SLSQP (from the NLOPT collection) and CSOLNP. The OpenMx Team’s version of OpenMx offers the choice of three optimizers: SLSQP, CSOLNP, and NPSOL.

**Usage**
```
mxComputeGradientDescent(freeSet = NA_character_, ..., engine = NULL,
fitfunction = "fitfunction", verbose = 0L, tolerance = NA_real_,
useGradient = NULL, warmStart = NULL, nudgeZeroStarts = mxOption(NULL,
"Nudge zero starts"), maxMajorIter = NULL, gradientAlgo = mxOption(NULL,
"Gradient algorithm"), gradientIterations = imxAutoOptionValue("Gradient iterations"),
gradientStepSize = imxAutoOptionValue("Gradient step size"))
```

**Arguments**
- `freeSet`: names of matrices containing free parameters.
- `...`: Not used. Forces remaining arguments to be specified by name.
- `engine`: specific 'NPSOL', 'SLSQP', or 'CSOLNP'
- `fitfunction`: name of the fitfunction (defaults to 'fitfunction')
- `verbose`: level of debugging output
tolerance: how close to the optimum is close enough (also known as the optimality tolerance)

useGradient: whether to use the analytic gradient (if available)

warmStart: a Cholesky factored Hessian to use as the NPSOL Hessian starting value (pre-conditioner)

nudgeZeroStarts: whether to nudge any zero starting values prior to optimization (default TRUE)

maxMajorIter: maximum number of major iterations

gradientAlgo: one of c('forward','central')

gradientIterations: number of Richardson iterations to use for the gradient

gradientStepSize: the step size for the gradient

Details

One of the most important options for SLSQP is gradientAlgo. By default, the central method is used. This method requires 2 times gradientIterations function evaluations per parameter per gradient. The central method can be much more accurate than the forward method, which requires gradientIterations function evaluations per parameter per gradient. The forward method is faster, and often works well enough, but can result in imprecise gradient estimations that may not allow SLSQP to fully optimize a given model, possibly resulting in code RED (status code 5 or 6).

Currently, only SLSQP uses arguments gradientIterations and gradientAlgo. CSOLNP always uses the forward method; NPSOL usually uses the forward method, but adaptively switches to central under certain circumstances.

CSOLNP uses the value of argument gradientStepSize as-is, whereas SLSQP internally scales it by a factor of 100. The purpose of this transformation is to obtain roughly the same accuracy given other differences in numerical procedure. NPSOL ignores gradientStepSize, and instead uses a function of mxOption “Function precision” to determine its gradient step size.

Currently, only SLSQP and NPSOL can use analytic gradients, and only NPSOL uses warmStart.

mxComputeHessianQuality

Compute the quality of the Hessian

Description

Tests whether the Hessian is positive definite (model$output$infoDefinite) and, if so, computes the approximate condition number (model$output$conditionNumber). See Luenberger & Ye (2008) Second Order Test (p. 190) and Condition Number (p. 239).

Usage

mxComputeHessianQuality(freeSet = NA_character_, ..., verbose = 0L)

Arguments

freeSet names of matrices containing free variables
... Not used. Forces remaining arguments to be specified by name.
verbose Level of debugging output.

Details

The condition number is approximated by $\text{norm}(H) \ast \text{norm}(H^{-1})$ where $H$ is the Hessian. The norm is either the 1- or infinity-norm (both obtain the same result due to symmetry).

References

mxComputeIterate

Repeatedly invoke a series of compute objects until change is less than tolerance.

Description

One step (typically the last) must compute the fit or maxAbsChange.

Usage

mxComputeIterate(steps, ..., maxIter = 500L, tolerance = 1e-09, verbose = 0L, freeSet = NA_character_, maxDuration = as.numeric(NA))

mxComputeNelderMead

Optimize parameters using a variation of the Nelder-Mead algorithm.

Description

OpenMx includes a flexible, options-rich implementation of the Nelder-Mead algorithm.

Usage

mxComputeNelderMead(
  freeSet=NA_character_, fitfunction="fitfunction", verbose=0L, nudgeZeroStarts=mxOption(NULL,"Nudge zero starts"), maxIter=NULL,...,
  alpha=1, beta0=0.5, beta1=0.5, gamma=2, sigma=0.5, bignum=1e35,
  iniSimplexType=c("regular","right","smartRight","random"),
  iniSimplexEdge=1, iniSimplexMat=NULL, greedyMinimize=FALSE,
  altContraction=FALSE, degenLimit=0, stagnCtrl=c(-1L,-1L), validationRestart=TRUE,
  xTolProx=1e-8, fTolProx=1e-8,
  doPseudoHessian=FALSE,
  ineqConstraintMthd=c("soft","eqMthd"),
  eqConstraintMthd=c("GDsearch","soft","backtrack","lp"),
  backtrackCtrl=c(0.5,5),
  centerIniSimplex=FALSE)
Arguments

freeSet Character-string names of MxMatrices containing free parameters.

fitfunction Character-string name of the fitfunction; defaults to ‘fitfunction’.

verbose Integer level of reporting printed to terminal at runtime; defaults to 0.

nudgeZeroStarts Should free parameters with start values of zero be "nudged" to 0.1 at runtime? Defaults to the current global value of mxOption "Nudge zero starts". May be a logical value, or one of character strings "Yes" or "No".

maxIter Integer maximum number of iterations. Value of NULL is accepted, in which case the value used at runtime will be 10 times the number of iterations specified by the effective value of mxOption "Major iterations".

... Not used. Forces remaining arguments to be specified by name.

alpha Numeric reflection coefficient. Must be positive. Defaults to 1.0.

betao, betai Numeric outside- and inside-contraction coefficients, respectively. Both must be within unit interval (0,1). Both default to 0.5.

gamma Numeric expansion coefficient. If positive, must be greater than alpha. If non-positive, expansion transformations will not be carried out. Defaults to 2.0.

sigma Numeric shrink coefficient. Cannot exceed 1.0. If non-positive, shrink transformations will not be carried out, and failed contractions will instead be followed by a simplex restart. Defaults to 0.5.

bignum Numeric value with which the fitfunction value is to be replaced if the fit is non-finite or is evaluated at infeasible parameter values. Defaults to 1e35.

iniSimplexType Character string naming the method by which to construct the initial simplex from the free-parameter start values. Defaults to "regular".

iniSimplexEdge Numeric edge-length of the initial simplex. Defaults to 1.0.

iniSimplexMat Optional numeric matrix providing the vertices of the initial simplex. The matrix must have as many columns as there are free parameters in the MxModel. The matrix’s number of rows must be no less than the number of free parameters minus the number of degrees-of-freedom gained from equality MxConstraints, if any. If a non-NULL value is provided, argument iniSimplexEdge is ignored, and argument iniSimplexType is only used in the case of a restart.

greedyMinimize Logical; should the optimizer use "greedy minimization?" Defaults to FALSE. See below for details.

altContraction Logical; should the optimizer use an "alternate contraction" transformation? Defaults to FALSE. See below for details.

degenLimit Numeric "degeneracy limit;" defaults to 0. If positive, the simplex will be restarted if the measure of the angle between any two of its edges is within 0 or pi by less than degenLimit.

stagnCtrl "Stagnation control;" integer vector of length 2; defaults to c(-1L, -1L). See below for details.

validationRestart Logical; defaults to TRUE.
**Details**

The state of a Nelder-Mead optimization problem is represented by a simplex (polytope) of $n + 1$ vertices in the space of the free parameters, where $n$ is the number of free parameters minus the number of degrees-of-freedom gained from equality MxConstraints. An iteration of the algorithm first sorts the $n + 1$ vertices by their corresponding fitfunction values (i.e., the values of the fitfunction when evaluated at each vertex), in ascending order (i.e., from "best" fit to "worst" fit). Then, the "subcentroid," which is the centroid of the "best" $n$ vertices, is calculated. Then, the algorithm attempts to improve upon the worst fit by transforming the simplex; see Singer & Nelder (2009) for details.

Argument iniSimplexType dictates how the initial simplex will be constructed from the start values if argument iniSimplexMat is NULL, and how the simplex will be re-initialized in the case of a restart. In all four cases, the vector of start values constitutes the "starting vertex" of the initial simplex. If iniSimplexType="regular", the initial simplex is merely a regular simplex with edge length equal to iniSimplexEdge. A "right" simplex is constructed by incrementing each free parameter by iniSimplexEdge from its starting value; thus, all the edges that intersect at the starting vertex do so at right angles. A "smartRight" simplex is constructed similarly, except that each free parameter is both incremented and decremented by iniSimplexEdge, and of those two points the one with the smaller fitfunction value is retained as a vertex. A "random" simplex is constructed by randomly perturbing the start values, in a manner similar to the default for mxTryHard(), to generate the coordinates of the other vertices. The user is advised that bounds on the free parameters may keep the initial simplex from having the requested regularity or edge-length, and that iniSimplexType is at best a suggestion in the presence of equality MxConstraints.

Note that if argument iniSimplexMat has nonzero length, the actual start values of the MxModel's free parameters are not used as a vertex of the initial simplex (unless one of the rows of iniSimplexMat happens to contain those start values).

If the simplex is restarted, a new simplex is constructed per argument iniSimplexType, with edge length equal to the distance between the current best and second-best vertices, and with the current best vertex used as the "first" vertex.
If \texttt{greedyMinimize=FALSE}, "greedy expansion" (Singer & Singer, 2004) is used: if the expansion point and reflection point both have smaller fitfunction values than the best vertex, the expansion point is accepted. If \texttt{greedyMinimize=TRUE}, "greedy minimization" (Singer & Singer, 2004) is used: if the expansion point and the reflection point both have smaller fitfunction values than the best vertex, the better of the two new points is accepted.

If argument \texttt{altContraction=TRUE}, the "modified contraction step" of Gill et al. (1982, Chapter 4) is used, and the candidate point is contracted toward the best vertex instead of toward the subcentroid.

If positive, the first element of argument \texttt{stagnCtrl} sets a threshold for the number of successive iterations in which the best vertex of the simplex does not change, after which the algorithm is said to be "stagnant" (in a sense similar to that of Kelley, 1999). To attempt to remedy the stagnation, the simplex is restarted. If positive, the second element of argument \texttt{stagnCtrl} sets threshold for the number of restarts conducted, beyond which stagnation no longer triggers a restart. The rationale for the second element is that the best vertex may not change for many iterations when the optimizer is close to convergence, under which circumstances restarting would be counterproductive, and in any event would require additional fitfunction evaluations.

If argument \texttt{validationRestart=TRUE}, then when the optimizer has successfully converged, it will restart the simplex and attempt to improve upon the tentative solution it already found. This validation restart (Gill et al., 1982, Chapter 4) always re-initializes the simplex as a regular simplex, centered on the best vertex of the tentative solution, with edge-length equal to the distance between the best and worst vertices of the tentative solution. Optimization proceeds until convergence to a solution with a better fit value, or \(2n\) iterations have elapsed.

The Nelder-Mead optimizer is considered to have successfully converged if (1) the largest \(l\)-infinity norm of the vector-differences between the best vertex and the other vertices is less than argument \texttt{xTolProx}, or (2) if the largest absolute difference in fit value between the best vertex and the other vertices is less than \texttt{fTolProx}.

If argument \texttt{doPseudoHessian=TRUE} and there are no equality \texttt{MxConstraints}, OpenMx will attempt to calculate the "pseudo-Hessian" or "curvature" matrix as described in the appendix to Nelder & Mead (1965). If successful, this matrix will be stored in the 'output' slot of the post-run \texttt{MxComputeNelderMead} object. Although crude, its inverse can be used as an estimate of the repeated-sampling covariance matrix of the free parameters when the usual finite-differences Hessian is unreliable.

OpenMx’s implementation of Nelder-Mead can handle nonlinear inequality \texttt{MxConstraints} reasonably well. Its default method for doing so, with argument \texttt{ineqConstraintMthd="soft"}, imposes a "soft" feasibility constraint by assigning a fitfunction value of \texttt{bignum} to points that violate the constraints by more than \texttt{mxOption 'Feasibility tolerance'}. Alternately, with argument \texttt{ineqConstraintMthd="eqMthd"}, inequality \texttt{MxConstraints} can be handled by the same method provided to argument \texttt{eqConstraintMthd}, whether or not equality \texttt{MxConstraints} are present.

OpenMx’s implementation of Nelder-Mead respects equality \texttt{MxConstraints}, but does not handle them especially well. Its effectiveness at handling equalities may be improved by providing a matrix to argument \texttt{iniSimplexMat} that ensures all of the initial vertices are feasible. If argument \texttt{eqConstraintMthd="GDsearch"} (the default), then whenever Nelder-Mead evaluates the fitfunction at an infeasible point, it initiates a subsidiary optimization that uses \texttt{SLSQP} to find the nearest (in squared Euclidean distance) feasible point, and replaces that feasible point for the infeasible one. The user should note that the function evaluations that occur during this subsidiary optimization are counted toward the total number of fitfunction evaluations during the
call to \texttt{mxRun()}. The effectiveness of the 'GDsearch' method is often improved by setting \texttt{mxOption 'Feasibility tolerance'} to a stricter (smaller) value than the on-load default. The method specified by \texttt{eqConstraintMthd="soft"} is described in the preceding paragraph. If argument \texttt{eqConstraintMthd="backtrack"}, then the optimizer attempts to backtrack from an infeasible point to a feasible point in a manner similar to that of Ghiasi et al. (2008), except that it used with \textit{all} new points, and not just those encountered via reflection, expansion and contraction. In this case, the displacement from the prior point to the candidate point is reduced by the proportion provided as the first element of argument \texttt{backtrackCtrl1}, and thus a new candidate point is considered. This process is repeated until feasibility of the candidate point is restored, or the number of attempts exceeds the second element of argument \texttt{backtrackCtrl1}. If argument \texttt{eqConstraintMthd="l1p"}, Nelder-Mead is used as part of an $l_1$-penalty algorithm, which as of this writing is somewhat experimental and may change in future releases of OpenMx. When using "$l1p", the simplex gradient and "pseudo-Hessian" are not calculated.

\textbf{Value}

Returns an object of class 'MxComputeNelderMead'.

\textbf{References}

\textbf{Examples}

\begin{verbatim}
foo <- mxComputeNelderMead()
str(Foo)
\end{verbatim}
mxComputeNothing

Description

This optimizer requires analytic 1st and 2nd derivatives of the fit function. Box constraints are supported. Parameters can approach box constraints but will not leave the feasible region (even by some small epsilon>0). Non-finite fit values are interpreted as soft feasibility constraints. That is, when a non-finite fit is encountered, line search is continued after the step size is multiplied by 10 available by increasing the verbose level.

Usage

mxComputeNewtonRaphson(freeSet = NA_character_, ..., fitfunction = "fitfunction", maxIter = 100L, tolerance = 1e-12, verbose = 0L)

Arguments

freeSet      names of matrices containing free variables
...          Not used. Forces remaining arguments to be specified by name.
fitfunction  name of the fitfunction (defaults to 'fitfunction')
maxIter      maximum number of iterations
tolerance    optimization is considered converged when the maximum relative change in fit is less than tolerance
verbose      level of debugging output

References

mxComputeNothing

Compute nothing

Description

Note that this compute plan actually does nothing whereas mxComputeOnce("expectation", "nothing") may remove the prediction of an expectation.

Usage

mxComputeNothing()
mxComputeNumericDeriv  Numerically estimate Hessian using Richardson extrapolation

Description

For N free parameters, Richardson extrapolation requires (iterations * (N^2 + N)) function evaluations. The implementation is closely based on the numDeriv R package.

Usage

mxComputeNumericDeriv(freeSet = NA_character_, ..., fitfunction = "fitfunction", parallel = TRUE, stepSize = imxAutoOptionValue("Gradient step size"), iterations = 4L, verbose = 0L, knownHessian = NULL, checkGradient = TRUE, hessian = TRUE)

Arguments

freeSet  names of matrices containing free variables
...  Not used. Forces remaining arguments to be specified by name.
fitfunction  name of the fitfunction (defaults to 'fitfunction')
parallel  whether to evaluate the fitfunction in parallel (defaults to TRUE)
stepSize  starting set size (defaults to 0.0001)
iterations  number of Richardson extrapolation iterations (defaults to 4L)
verbose  Level of debugging output.
knownHessian  an optional matrix of known Hessian entries
checkGradient  whether to check the first order convergence criterion (gradient is near zero)
hessian  whether to estimate the Hessian. If FALSE then only the gradient is estimated.

Details

In addition to an estimate of the Hessian, forward, central, and backward estimates of the gradient are made available in this compute plan's output slot.

When checkGradient=TRUE, the central difference estimate of the gradient is used to determine whether the first order convergence criterion is met. In addition, the forward and backward difference estimates of the gradient are compared for symmetry. When sufficient asymmetry is detected, the standard error is flagged. In the case, profile likelihood confidence intervals should be used for inference instead of standard errors (see mxComputeConfidenceInterval).
Examples

```r
library(OpenMx)
data(demoOneFactor)
factorModel <- mxModel(name = "One Factor",
                      mxMatrix(type = "Full", nrow = 5, ncol = 1, free = FALSE, values = .2, name = "A"),
                      mxMatrix(type = "Symm", nrow = 1, ncol = 1, free = FALSE, values = 1 , name = "L"),
                      mxMatrix(type = "Diag", nrow = 5, ncol = 5, free = TRUE , values = 1 , name = "U"),
                      mxAlgebra(A %*% L %*% t(A) + U, name = "R"),
                      mxExpectationNormal(covariance = "R", dimnames = names(demoOneFactor)),
                      mxFitFunctionML(),
                      mxData(cov(demoOneFactor), type = "cov", numObs = 500),
                      mxComputeSequence(
                       list(mxComputeNumericDeriv(), mxComputeReportDeriv())
                      )
)
factorModelFit <- mxRun(factorModel)
factorModelFit$output$hessian
```

**mxComputeOnce**  
*Compute something once*

**Description**

Some models are optimized for a sparse Hessian. Therefore, it can be much more efficient to compute the inverse Hessian in comparison to computing the Hessian and then inverting it.

**Usage**

```r
mxComputeOnce(from, what = NULL, how = NULL, ..., freeSet = NA_character_,
                verbose = 0L, .is.bestfit = FALSE)
```

**Arguments**

- `from` the object to perform the computation (a vector of expectation or fit function names)
- `what` what to compute
- `how` to compute it (optional)
- `...` Not used. Forces remaining arguments to be specified by name.
- `freeSet` names of matrices containing free variables
- `verbose` the level of debugging output
- `is.bestfit` do not use; for backward compatibility

**Details**

The information matrix is only valid when parameters are at the maximum likelihood estimate. The information matrix is returned in model$output$hessian. You cannot request both the information matrix and the Hessian. The information matrix is invariant to the sign of the log likelihood scale whereas the Hessian is not. Use the `how` parameter to specify which approximation to use (one of "default", "hessian", "sandwich", "bread", and "meat").
Examples

```r
data(demoOneFactor)
factorModel <- mxModel(name ="One Factor",
             mxMatrix(type="Full", nrow=5, ncol=1, free=TRUE, values=0.2, name="A"),
             mxMatrix(type="Symm", nrow=1, ncol=1, free=FALSE, values=1, name="L"),
             mxMatrix(type="Diag", nrow=5, ncol=5, free=TRUE, values=1, name="U"),
             mxAlgebra(expression=A %*% L %*% t(A) + U, name="R"),
             mxFitFunctionML(),mxExpectationNormal(covariance="R", dimnames=names(demoOneFactor)),
             mxData(observed=cov(demoOneFactor), type="cov", numObs=500),
             mxComputeOnce('fitfunction', 'fit'))
factorModelFit <- mxRun(factorModel)
factorModelFit$output$fit # 972.15
```

mxComputeReportDeriv  Report derivatives

Description

Copy the internal gradient and Hessian back to R.

Usage

```r
mxComputeReportDeriv(freeSet = NA_character_)
```

Arguments

```r
freeSet       names of matrices containing free variables
```

mxComputeReportExpectation  Report expectation

Description

Copy the internal model expectations back to R.

Usage

```r
mxComputeReportExpectation(freeSet = NA_character_)
```

Arguments

```r
freeSet       names of matrices containing free variables
```
**mxComputeSequence**  
 Invoke a series of compute objects in sequence

**Description**

Invoke a series of compute objects in sequence

**Usage**

```r
mxComputeSequence(steps = list(), ..., freeSet = NA_character_,
independent = FALSE)
```

**Arguments**

- `steps` a list of compute objects
- `...` Not used; forces argument 'freeSet' to be specified by name.
- `freeSet` Names of matrices containing free parameters.
- `independent` Whether the steps could be executed out-of-order.

---

**mxComputeStandardError**  
Compute standard errors given the Hessian or inverse Hessian

**Description**

The fit is assumed to be in deviance units (-2 log likelihood).

**Usage**

```r
mxComputeStandardError(freeSet = NA_character_)
```

**Arguments**

- `freeSet` names of matrices containing free variables
Description

The provided compute plan is run until the status code indicates success (0 or 1). It gives up after a small number of retries.

Usage

```r
mxComputeTryHard(plan, ..., freeSet = NA_character_, verbose = 0L,
                  location = 1, scale = 0.25, maxRetries = 3L)
```

Arguments

- **plan**: compute plan to optimize the model
- **...**: Not used. Forces remaining arguments to be specified by name.
- **freeSet**: names of matrices containing free variables
- **verbose**: level of debugging output
- **location**: location of the perturbation distribution
- **scale**: scale of the perturbation distribution
- **maxRetries**: maximum number of plan evaluations per invocation (including the first evaluation)

Details

Upon failure, start values are randomly perturbed. Currently only the uniform distribution is implemented. The distribution is parametrized by arguments `location` and `scale`. The `location` parameter is the distribution’s median. For the uniform distribution, `scale` is the absolute difference between its median and extrema (i.e., half the width of the rectangle). Each start value is multiplied by a random draw and then added to a random draw from a distribution with the same `scale` but with a median of zero.

<td>Not used. Helps OpenMx catch bad input to argument expression, and requires argument jac—meant for advanced users—to be specified by name.</td>
</tr>
<tr>
<td>jac</td>
<td>An optional character string naming the MxAlgebra or MxMatrix representing the Jacobian for the constraint function.</td>
</tr>
</tbody>
</table>

Details

The mxConstraint() function defines relationships between two MxAlgebra or MxMatrix objects. They are used to affect the estimation of free parameters in the referenced objects. The constraint relation is written identically to how a MxAlgebra expression would be written. The outermost operator in this relation must be either ‘<’, ‘==’ or ‘>’. To affect an estimation or optimization, an MxConstraint object must be included in an MxModel object with all referenced MxAlgebra and MxMatrix objects.

Usage Note: Use of mxConstraint() should be avoided where it is possible to achieve the constraint by equating free parameters by label or position in an MxMatrix or MxAlgebra object. Including mxConstraints in an mxModel will disable standard errors and the calculation of the final Hessian, and thus should be avoided when standard errors are of importance. Constraints also add computational overhead. If one labels two parameters the same, the optimizer has one fewer parameter to optimize. However, if one uses mxConstraint to do the same thing, both parameters remain estimated and a Lagrangian multiplier is added to maintain the constraint. This constraint also has to have its gradients computed and the order of the Hessian grows as well. So while both approaches should work, the mxConstraint() will take longer to do so.

Alternatives to mxConstraints include using labels, lbound or ubound arguments or algebras. Free parameters in the same MxModel may be constrained to equality by giving them the same name in their respective ‘labels’ matrices. Similarly, parameters may be fixed to an individual element in a MxModel object or the result of an MxAlgebra object through labeling. For example, assigning a label of “name[1,1]” fixes the value of a parameter at the value in first row and first column of the matrix or algebra “name”. The mxConstraint function should be used to enforce inequalities that cannot be conveyed using other methods.

Argument jac is used to provide the name of an MxMatrix or MxAlgebra that equals the matrix of first derivatives—the Jacobian—of the constraint function with respect to the free parameters. Here,
the "constraint function" refers to the constraint expression in canonical form, with an arbitrary matrix expression on the left-hand side of the comparator, and a matrix with the same dimensions, and constant with respect to free parameters (typically, a matrix of zeroes), on the right-hand side. The rows of the Jacobian correspond to elements of the matrix result of the right-hand side, in column-major order. Each row of the Jacobian is the vector of first partial derivatives, with respect to the free parameters of the MxModel, of its corresponding element. Each column of the Jacobian corresponds to a free parameter of the MxModel; each column must be named with the label of the corresponding free parameter. Only the gradient-descent optimizers NPSOL and SLSQP are able to take advantage of user-supplied Jacobians.

Value

Returns an MxConstraint object.

# Force the fixed parameter in matrix G to be the result of the algebra
end <- mxMatrix("Full", 1, 1, free=FALSE, values=1, labels="logP[1,1]", name="G")

MxConstraint-class  
Class "MxConstraint"

**Description**

MxConstraint is an S4 class. An MxConstraint object is a named entity. New instances of this class can be created using the function `mxConstraint()`.

**Details**

Slots may be referenced with the $ symbol. See the documentation for Classes and the examples in the mxConstraint document for more information.

**Slots**

- **name**: Character string; the name of the object.
- **formula**: Object of class "MxAlgebraFormula". The MxAlgebra-like expression representing the constraint function.
- **alg1**: Object of class "MxCharOrNumber". For internal use.
- **alg2**: Object of class "MxCharOrNumber". For internal use.
- **relation**: Object of class "MxCharOrNumber". For internal use.
- **jac**: Object of class "MxCharOrNumber". Identifies the MxAlgebra representing the Jacobian for the constraint function.
- **linear**: Logical. For internal use.

**Methods**

- `$<-` signature(x = "MxConstraint")
- `$` signature(x = "MxConstraint")
- `imxDeparse` signature(object = "MxConstraint")
- `names` signature(x = "MxConstraint")
- `print` signature(x = "MxConstraint")
- `show` signature(object = "MxConstraint")

### mxData

Create MxData Object

**Description**

This function creates a new MxData object.

**Usage**

```r
mxData(observed, type, means = NA, numObs = NA, acov=NA, fullWeight=NA,
thresholds=NA, ..., sort=NA, primaryKey = as.character(NA),
weight = as.character(NA))
```

**Arguments**

- **observed**: A matrix or data.frame which provides data to the MxData object.
- **type**: A character string defining the type of data in the `observed` argument. Must be one of “raw”, “cov”, or “cor”.
- **means**: An optional vector of means for use when `type` is “cov”, or “cor”.
- **numObs**: The number of observations in the data supplied in the `observed` argument. Required unless `type` equals “raw”.
- **acov**: Asymptotic covariance matrix of observed, means, and thresholds. Used for weighted least squares at weight matrix.
- **fullWeight**: Full asymptotic covariance matrix of observed, means, and thresholds. Used for weighted least squares in standard error and quasi-chi-squared calculation.
- **thresholds**: Observed thresholds. Used for weighted least squares with ordinal data.
- **...**: Not used. Forces remaining arguments to be specified by name.
- **sort**: Whether to sort raw data prior to use (default NA)
- **primaryKey**: The column name of the primary key used to uniquely identify rows (default NA)
- **weight**: The column name containing the row weights
Details

The mxData function creates MxData objects, which can be used as arguments in MxModel objects. The ‘observed’ argument may take either a data frame or a matrix, which is then described with the ‘type’ argument. Data types describe compatibility and usage with expectation functions in MxModel objects. Four different data types are supported (a fifth, sscp, is not yet implemented):

- **raw**: The contents of the ‘observed’ argument are treated as raw data. Missing values are permitted and must be designated as the system missing value. The ‘means’ and ‘numObs’ arguments cannot be specified, as the ‘means’ argument is not relevant and the ‘numObs’ argument is automatically populated with the number of rows in the data. Data of this type may use fit functions such as mxFitFunctionML function in MxModel objects, which will automatically use covariance estimation under full-information maximum likelihood for this data type.

- **cov**: The contents of the ‘observed’ argument are treated as a covariance matrix. The ‘means’ argument is not required, but may be included for estimations involving means. The ‘numObs’ argument is required, which should reflect the number of observations or rows in the data described by the covariance matrix. Data of this type may use the fit functions such as mxFitFunctionML, depending on the specified model.

- **cor**: The contents of the ‘observed’ argument are treated as a correlation matrix. The ‘means’ argument is not required, but may be included for estimations involving means. The ‘numObs’ argument is required, which should reflect the number of observations or rows in the data described by the covariance matrix. Data of this type may use the fit functions such as mxFitFunctionML functions, depending on the specified model.

- **acov**: The best way to have data of the type is to use the mxDataWLS function. The contents of the ‘observed’ argument are treated as the polychoric correlation matrix of the ordinal variables. The ‘means’ argument is not required, but may be included for estimations involving means. The ‘thresholds’ argument is not required, but may be included for estimation involving thresholds and ordinal variables. The ‘numObs’ argument is required, which should reflect the number of observations or rows in the data described by the polychoric correlation matrix. Data of this type almost certainly use the mxFitFunctionWLS function, but may depend on the specified model.

MxData objects may not be included in MxAlgebra objects or use the mxFitFunctionAlgebra function. If these capabilities are desired, data should be appropriately input or transformed using the mxMatrix and mxAlgebra functions.

While column names are stored in the ‘observed’ slot of MxData objects, these names are not recognized as variable names in MxPath objects. Variable names must be specified using the ‘manifestVars’ argument of the mxModel function prior to use in MxPath objects.

The mxData function does not currently place restrictions on the size, shape, or symmetry of matrices input into the ‘observed’ argument. While it is possible to specify MxData objects as covariance or correlation matrices that do not have the properties commonly associated with these matrices, failure to correctly specify these matrices will likely lead to problems in model estimation.

OpenMx uses the names of variables to map them onto the expectation functions and other elements associated with your model. For data.frames, ensure you have set the names(). For matrices set names using, for instance, row.names=c("your", "columns"). Covariance and correlation matrices need to have both the row and column names set and these must be identical, for instance by using dimnames=list(varNames, varNames).
In the case of raw data, the optional ‘weight’ argument names a column in the ‘observed’ data that contains per-row weights. For data with many repeated response patterns, model evaluation time can be reduced.

When a primary key is provided, sorting is disabled. Otherwise, sort defaults to TRUE.

**Value**

Returns a new MxData object.

**References**

                    mxExpectationNormal(covariance="expCov", dimnames=covNames),
                    mxFitFunctionML(),
                    testData)

outModel <- mxRun(testModel)

summary(outModel)
MxData-class

Description

MxData is an S4 class. An MxData object is a named entity. New instances of this class can be created using the function `mxData`. MxData is an S4 class union. An MxData object is either NULL or a MxNonNullData object.

Details

The MxNonNullData class has the following slots:

- **name**: The name of the object
- **observed**: Either a matrix or a data frame
- **vector**: A vector for means, or NA if missing
- **type**: Either 'raw', 'cov', or 'cor'
- **numObs**: The number of observations

The 'name' slot is the name of the MxData object.

The 'observed' slot is used to contain data, either as a matrix or as a data frame. Use of the data in this slot by other functions depends on the value of the 'type' slot. When 'type' is equal to 'cov' or 'cor', the data input into the 'matrix' slot should be a symmetric matrix or data frame.

The 'vector' slot is used to contain a vector of numeric values, which is used as a vector of means for MxData objects with 'type' equal to 'cov' or 'cor'. This slot may be used in estimation using the `mxFitFunctionML` function.

The 'type' slot may take one of four supported values:

- **raw**: The contents of the 'observed' slot are treated as raw data. Missing values are permitted and must be designated as the system missing value. The 'vector' and 'numObs' slots cannot be specified, as the 'vector' argument is not relevant and the 'numObs' argument is automatically populated with the number of rows in the data. Data of this type may use the `mxFitFunctionML` function as its fit function in MxModel objects, which can deal with covariance estimation under full-information maximum likelihood.

- **cov**: The contents of the 'observed' slot are treated as a covariance matrix. The 'vector' argument is not required, but may be included for estimations involving means. The 'numObs' slot is required. Data of this type may use fit functions such as the `mxFitFunctionML`, depending on the specified model.

- **cor**: The contents of the 'observed' slot are treated as a correlation matrix. The 'vector' argument is not required, but may be included for estimations involving means. The 'numObs' slot is required. Data of this type may use fit functions such as the `mxFitFunctionML`, depending on the specified model.
mxDataDynamic

The 'numObs' slot describes the number of observations in the data. If 'type' equals 'raw', then 'numObs' is automatically populated as the number of rows in the matrix or data frame in the 'observed' slot. If 'type' equals 'cov' or 'cor', then this slot must be input using the 'numObs' argument in the mxData function when the MxData argument is created.

MxData objects may not be included in MxAlgebra objects or use the mxFitFunctionAlgebra function. If these capabilities are desired, data should be appropriately input or transformed using the mxMatrix and mxAlgebra functions.

While column names are stored in the 'observed' slot of MxData objects, these names are not recognized as variable names in MxPath objects. Variable names must be specified using the 'manifestVars' argument of the mxModel function prior to use in MxPath objects.

The mxData function does not currently place restrictions on the size, shape, or symmetry of matrices input into the 'observed' argument. While it is possible to specify MxData objects as covariance or correlation matrices that do not have the properties commonly associated with these matrices, failure to correctly specify these matrices will likely lead to problems in model estimation.

MxDataFrameOrMatrix-class

MxDataFrameOrMatrix

Description

Internal class that is the union of data.frame and matrix.

Details

Not to be used.

MxDataStatic-class

Create static data

Description

Internal static data class.

Details

Not to be used.

mxDataWLS

Create MxData Object for Least Squares (WLS, DWLS, ULS) Analyses

Description

This function creates a new MxData object of type “ULS” (unweighted least squares), “WLS” (weighted least squares) or “DWLS” (diagonally-weighted least squares). The appropriate fit function to include with these models is mxFitFunctionWLS

Usage

mxDataWLS(data, type = "WLS", useMinusTwo = TRUE, returnInverted = TRUE, fullWeight = TRUE, suppressWarnings = TRUE, allContinuousMethod = "cumulants")
Arguments

- **data**: A matrix or data.frame which provides raw data to be used for WLS.
- **type**: A character string 'WLS' (default), 'DWLS', or 'ULS' for weighted, diagonally weighted, or unweighted least squares, respectively.
- **useMinusTwo**: Logical indicating whether to use -2LL (default) or -LL.
- **returnInverted**: Logical indicating whether to return the information matrix (default) or the covariance matrix.
- **fullWeight**: Logical determining if the full weight matrix is returned (default). Needed for standard error and quasi-chi-squared calculation.
- **suppressWarnings**: Logical that determines whether to suppress diagnostic warnings. These warnings are likely only helpful to developers.
- **allContinuousMethod**: A character string 'cumulants' (default) or 'marginals'. See Details.

Details

The mxDataWLS function creates an MxData object, which can be used in MxModel objects. This function takes raw data and returns an MxData object to be used in a model to fit with weighted least squares.

Both Ordinal and continuous data are supported. A combination of these data types also succeeds. Early tests suggested that full 'WLS' might be biased in this joint ordinal and continuous case, whereas 'ULS' and 'DWLS' were unbiased. However further investigation revealed that all of these were unbiased when the model is correct, but full 'WLS' is highly sensitive to model mis-specification. Full 'WLS' can heavily weight the fourth-order moments of the distribution, so small deviations between the observed fourth-order moments and those implied by the model can lead to poor estimates.

By default when only continuous variables are present, the argument allContinuousMethod dictates that the asymptotically distribution free (ADF) method of Browne (1984) is used. This method computes the fourth order cumulants for the weight matrix: thus, the name. The method does not readily handle missing data and does not return weights or summary statistics for the means, but it is generally fast and ADF up to elliptical distributions. The other option, 'marginals', uses similar methods to the ordinal and joint ordinal-continuous cases. It does return weights and summary statistics for the means. When there are any ordinal variables present, allContinuousMethod is ignored.

Value

Returns a new MxData object.

Examples

```r
# Create and fit a model using mxMatrix, mxAlgebra, mxExpectationNormal, and mxFitFunctionWLS
library(OpenMx)

# Simulate some data
x=rnorm(1000, mean=0, sd=1)
y= 0.5*x + rnorm(1000, mean=0, sd=1)
tmpFrame <- data.frame(x, y)
tmpNames <- names(tmpFrame)
wdata <- mxDataWLS(tmpFrame)

# Define the matrices
S <- mxMatrix(type = "Full", nrow = 2, ncol = 2, values=c(1,0,0,1),
              free=c(TRUE,FALSE,FALSE,TRUE), labels=c("Vx", NA, NA, "Vy"), name = "S")
A <- mxMatrix(type = "Full", nrow = 2, ncol = 2, values=c(0,1,0,0),
              free=c(FALSE,TRUE,FALSE,FALSE), labels=c(NA, "b", NA, NA), name = "A")
I <- mxMatrix(type="Iden", nrow=2, ncol=2, name="I")

# Define the expectation
expCov <- mxAlgebra(solve(I-A) %*% S %*% t(solve(I-A)), name="expCov")
expFunction <- mxExpectationNormal(covariance="expCov", dimnames=tmpNames)

# Choose a fit function
fitFunction <- mxFitFunctionWLS()

# Define the model
tmpModel <- mxModel(model="exampleModel", S, A, I, expCov, expFunction, fitFunction, wdata)

# Fit the model and print a summary
tmpModelOut <- mxRun(tmpModel)
summary(tmpModelOut)
```
MxDirectedGraph-class  

**Description**

This is an internal class and should not be used directly. It is a class for directed graphs.

---

**mxEval**  
*Evaluate Values in MxModel*

**Description**

This function can be used to evaluate an arbitrary R expression that includes named entities from a **MxModel** object, or labels from a **MxMatrix** object.

**Usage**

```r
mxEval(expression, model, compute = FALSE, show = FALSE, defvar.row = 1, 
cache = new.env(parent = emptyenv()), cacheBack = FALSE)
mxEvalByName(name, model, compute = FALSE, show = FALSE, defvar.row = 1, 
cache = new.env(parent = emptyenv()), cacheBack = FALSE)
```

**Arguments**

- `expression`  
  An arbitrary R expression.

- `model`  
  The model in which to evaluate the expression.

- `compute`  
  If TRUE then compute the value of algebra expressions and populate square bracket substitutions.

- `show`  
  If TRUE then print the translated expression.

- `defvar.row`  
  The row number for definition variables when compute=TRUE; defaults to 1. When compute=FALSE, values for definition variables are always taken from the first (i.e., first before any automated sorting is done) row of the raw data.

- `cache`  
  An R environment of matrix values used to speedup computation.

- `cacheBack`  
  If TRUE then return the list pair (value, cache).

- `name`  
  The character name of an object to evaluate.
Details

The argument ‘expression’ is an arbitrary R expression. Any named entities that are used within the R expression are translated into their current value from the model. Any labels from the matrices within the model are translated into their current value from the model. Finally the expression is evaluated and the result is returned. To enable debugging, the ‘show’ argument has been provided. The most common mistake when using this function is to include named entities in the model that are identical to R function names. For example, if a model contains a named entity named ‘c’, then the following mxEval call will return an error: mxEval(c(A, B, C), model).

The mxEvalByName function is a wrapper around mxEval that takes a character instead of an R expression.

If ‘compute’ is FALSE, then MxAlgebra expressions return their current values as they have been computed by the optimization call (using mxRun). If the ‘compute’ argument is TRUE, then MxAlgebra expressions will be calculated in R and square bracket substitutions will be performed. Any references to an objective function that has not yet been calculated will return a 1 x 1 matrix with a value of NA.

The ‘cache’ is used to speedup calculation by storing previously computing values. The cache is a list of matrices, such that names(cache) must all be of the form “modelname.entityname”. Setting ‘cacheBack’ to TRUE will return the pair list(value, cache) where value is the result of the mxEval() computation and cache is the updated cache.

mxAlgebra to create algebraic expressions inside your model and mxModel for the model object mxEval looks inside when evaluating.

Examples

library(OpenMx)

# Set up a 1x1 matrix
matrixA <- mxMatrix("Full", nrow = 1, ncol = 1, values = 1, name = "A")

# Set up an algebra
algebraB <- mxAlgebra(A + A, name = "B")

# Put them both in a model
testModel <- mxModel(model="testModel", matrixA, algebraB)

# Even though the model has not been run, we can evaluate the algebra
# given the starting values in matrixA.
mxEval(B, testModel, compute=TRUE)

# If we just print the algebra, we can see it has not been evaluated
testModel$B
Evaluate an algebra on an abscissa grid and collect column results

Description

This function evaluates an algebra on a grid of points provided in an auxiliary abscissa matrix.

Usage

```r
mxEvaluateOnGrid(algebra, abscissa)
```

Arguments

- `algebra`: the name of the single column matrix to be evaluated.
- `abscissa`: the name of the abscissa matrix. See details.

Details

The abscissa matrix must be in a specific format. The variables are in the rows. Abscissa row names must match names of free variables. The grid points are in columns. For each point (column), the free variables are set to the given values and the algebra is re-evaluated. The resulting columns are collected as the result.

Value

Returns the collected columns.

Examples

```r
library(OpenMx)

test2 <- mxModel("test2",
mxMatrix(values=1.1, nrow=1, ncol=1, free=TRUE, name="thang"),
mxMatrix(nrow=1, ncol=1, labels="abscissa1", free=TRUE, name="currentAbscissa"),
mxMatrix(values=-2:2, nrow=1, ncol=5, name="abscissa",
  dimnames=list(c('abscissa1'), NULL)),
mxAlgebra(rbind(currentAbscissa + thang, currentAbscissa * thang), name="stuff"),
mxAlgebra(mxEvaluateOnGrid(stuff, abscissa), name="grid")

test2 <- mxRun(test2)
omxCheckCloseEnough(test2$grid$result, matrix(c(-1:3 + .1, -2:2 * 1.1), ncol=5, nrow=2,byrow=TRUE))
```
MxExpectation-class  

MxExpectation

Description
This is an internal class and should not be used directly.

mxExpectationBA81  

Create a Bock & Aitkin (1981) expectation

Description
Used in conjunction with mxFitFunctionML, this expectation models ordinal data with a modest number of latent dimensions. Currently, only a multivariate Normal latent distribution is supported. An equal-interval quadrature is used to integrate over the latent distribution. When all items use the graded response model and items are assumed conditionally independent then item factor analysis is equivalent to a factor model.

Usage
mxExpectationBA81(ItemSpec, item = "item", ..., qpoints = 49L, qwidth = 6, mean = "mean", cov = "cov", verbose = 0L, weightColumn = NA_integer_, EstepItem = NULL, debugInternal = FALSE)

Arguments

ItemSpec     a single item model (to replicate) or a list of item models in the same order as the column of ItemParam
item         the name of the mxMatrix holding item parameters with one column for each item model with parameters starting at row 1 and extra rows filled with NA
...          Not used. Forces remaining arguments to be specified by name.
qpoints      number of points to use for equal interval quadrature integration (default 49L)
qwidth       the width of the quadrature as a positive Z score (default 6.0)
mean         the name of the mxMatrix holding the mean vector
cov          the name of the mxMatrix holding the covariance matrix
verbose      the level of runtime diagnostics (default 0L)
weightColumn the name of the column in the data containing the row weights (DEPRECATED)
EstepItem    a simple matrix of item parameters for the E-step. This option is mainly of use for debugging derivatives.
debugInternal when enabled, some of the internal tables are returned in $debug. This is mainly of use to developers.
The conditional likelihood of response $x_{ij}$ to item $j$ from person $i$ with item parameters $\xi_j$ and latent ability $\theta_i$ is

$$L(x_i|\xi, \theta_i) = \prod_j Pr(\text{pick} = x_{ij}|\xi_j, \theta_i).$$

Items are assumed conditionally independent. That is, the outcome of one item is assumed to not influence another item after controlling for $\xi$ and $\theta_i$. The unconditional likelihood is obtained by integrating over the latent distribution $\theta_i$,

$$L(x_i|\xi) = \int L(x_i|\xi, \theta_i)L(\theta_i)d\theta_i.$$

With an assumption that examinees are independently and identically distributed, we can sum the individual log likelihoods,

$$\mathcal{L} = \sum_i \log L(x_i|\xi).$$

Response models $Pr(\text{pick} = x_{ij}|\xi_j, \theta_i)$ are not implemented in OpenMx, but are imported from the RPF package. You must pass a list of models obtained from the RPF package in the ‘ItemSpec’ argument. All item models must use the same number of latent factors although some of these factor loadings can be constrained to zero in the item parameter matrix. The ‘item’ matrix contains item parameters with one item per column in the same order at ItemSpec.

The ‘qpoints’ and ‘qwidth’ argument control the fineness and width, respectively, of the equal-interval quadrature grid. The integer ‘qpoints’ is the number of points per dimension. The quadrature extends from negative qwidth to positive qwidth for each dimension. Since the latent distribution defaults to standard Normal, qwidth can be regarded as a value in Z-score units.

The optional ‘mean’ and ‘cov’ arguments permit modeling of the latent distribution in multigroup models (in a single group, the latent distribution must be fixed). A separate latent covariance model is used in combination with mxExpectationBA81. The point mass distribution contained in the quadrature is converted into a multivariate Normal distribution by mxDataDynamic. Typically mxExpectationNormal is used to fit a multivariate Normal model to these data. Some intricate programming is required. Examples are given in the manual. mxExpectationBA81 uses a sample size of $N$ for the covariance matrix. This differs from mxExpectationNormal which uses a sample size of $N - 1$.

The ‘verbose’ argument enables diagnostics that are mainly of interest to developers.

When a two-tier covariance matrix is recognized, this expectation automatically enables analytic dimension reduction (Cai, 2010).

The optional ‘weightColumn’ is superceded by the weight argument in mxData. For data with many repeated response patterns, model evaluation time can be reduced. An easy way to transform your data into this form is to use compressDataFrame. Non-integer weights are supported except for EAPscores.

mxExpectationBA81 requires mxComputeEM. During a typical optimization run, latent abilities are assumed for examinees during the E-step. These examinee scores are implied by the previous
iteration’s parameter vector. This can be overridden using the ‘EstepItem’ argument. This is mainly of use to developers for checking item parameter derivatives.

Common univariate priors are available from `univariatePrior`. The standard Normal distribution of the quadrature acts like a prior distribution for difficulty. It is not necessary to impose any additional Bayesian prior on difficulty estimates (Baker & Kim, 2004, p. 196).

Many estimators are available for standard errors. Oakes is recommended (see `mxComputeEM`). Also available are Supplement EM (`mxComputeEM`), Richardson extrapolation (`mxComputeNumericDeriv`), likelihood-based confidence intervals (`mxCI`), and the covariance of the rowwise gradients.

mxExpectationGREML Create MxExpectationGREML Object

Description

This function creates a new MxExpectationGREML object.

Usage

mxExpectationGREML(V, yvars=character(0), Xvars=list(), addOnes=TRUE, blockByPheno=TRUE,
  staggerZeroes=TRUE, dataset.is.yX=FALSE, casesToDropFromV=integer(0))

Arguments

V Character string: the name of the MxAlgebra or MxMatrix to serve as the 'V' matrix (the model-expected covariance matrix). Internally, the 'V' matrix is assumed to be symmetric, and its elements above the main diagonal are ignored.

yvars, Xvars, addOnes, blockByPheno, staggerZeroes
Passed to mxGREMLDataHandler().

dataset.is.yX Logical; defaults to FALSE. If TRUE, then the first column of the raw dataset is taken as-is to be the 'y' phenotype vector, and the remaining columns are taken as-is to be the 'X' matrix of covariates. In this case, mxGREMLDataHandler() is never internally called at runtime, and all other arguments besides V and casesToDropFromV are ignored.
casesToDropFromV

Integer vector. Its elements are the numbers of the rows and columns of covariance matrix 'V' to be dropped at runtime, usually because they correspond to rows of 'y' or 'X' that contained missing observations. By default, no cases are dropped from 'V.' Ignored unless dataset.is.yX=TRUE.

Details

"GREML" stands for "genomic-relatedness-matrix restricted maximum-likelihood." In the strictest sense of the term, it refers to genetic variance-component estimation from matrices of subjects' pairwise degree of genetic relatedness, as calculated from genome-wide marker data. It is from this original motivation that some of the terminology originates, such as calling 'y' the "phenotype" vector. However, OpenMx's implementation of GREML is applicable for analyses from any subject-matter domain, and in which the following assumptions are reasonable:

1. Conditional on 'X' (the covariates), the phenotype vector (response variable) 'y' is a single realization from a multivariate-normal distribution having (in general) a dense covariance matrix, 'V.'
2. The parameters of the covariance matrix, such as variance components, are of primary interest.
3. The random effects are normally distributed.
4. Weighted least-squares regression, using the inverse of 'V' as a weight matrix, is an adequate model for the phenotypic means. Note that the regression coefficients are not actually free parameters to be numerically optimized.

Computationally, the chief distinguishing feature of an OpenMx GREML analysis is that the phenotype vector, 'y,' is a single realization of a random vector that, in general, cannot be partitioned into independent subvectors. For this reason, definition variables are not compatible (and should be unnecessary with) GREML expectation. GREML expectation can still be used if the covariance matrix is sparse, but as of this writing, OpenMx does not take advantage of the sparseness to improved performance. Because of the limitations of restricted maximum likelihood, GREML expectation is presently incompatible with ordinal variables.

Value

Returns a new object of class MxExpectationGREML.

References

MxExpectationGREML-class

Class "MxExpectationGREML"

Description

MxExpectationGREML is a type of expectation class. It contains the necessary elements for specifying a GREML model. For more information, see mxExpectationGREML().

Objects from the Class

Objects can be created by calls of the form mxExpectationGREML(V, yvars, Xvars, addOnes, blockByPheno,

Slots

V: Object of class "MxCharOrNumber". Identifies the MxAlgebra or MxMatrix to serve as the 'V' matrix.
yvars: Character vector. Each string names a column of the raw dataset, to be used as a phenotypes.
Xvars: A list of data column names, specifying the covariates to be used with each phenotype.
addOnes: Logical; pertains to data-handling at runtime.
blockByPheno: Logical; pertains to data-handling at runtime.
staggerZeroes: Logical; pertains to data-handling at runtime.
dataset.is.yX: Logical; pertains to data-handling at runtime.
y: Object of class "MxData". Its observed slot will contain the phenotype vector, 'y.'
X: A matrix, to contain the 'X' matrix of covariates.
yXcolnames: Character vector; used to store the column names of 'y' and 'X.'
casesToDrop: Integer vector, specifying the rows and columns of the 'V' matrix to be removed at runtime.
b: A matrix, to contain the vector of regression coefficients calculated at runtime.
bcov: A matrix, to contain the sampling covariance matrix of the regression coefficients calculated at runtime.
numFixEff: Integer number of covariates in 'X.'
dims: Object of class "character".
numStats: Numeric; number of observed statistics.
dataColumns: Object of class "numeric".
name: Object of class "character".
data: Object of class "MxCharOrNumber".
.runDims: Object of class "character".

Extends

Class "MxBaseExpectation", directly. Class "MxBaseNamed", by class "MxBaseExpectation", distance 2. Class "MxExpectation", by class "MxBaseExpectation", distance 2.

Methods

No methods defined with class "MxExpectationGREML" in the signature.

References

The OpenMx User's guide can be found at http://openmx.ssri.psu.edu/documentation.

See mxExpectationGREML() for creating MxExpectationGREML objects, and for more information generally concerning GREML analyses, including a complete example. More information about the OpenMx package may be found here.

Examples

showClass("MxExpectationGREML")
**mxExpectationHiddenMarkov**

*Hidden Markov expectation*

**Description**

Used in conjunction with `mxFitFunctionML`, this expectation can express a mixture model (with the transition matrix omitted) or a Hidden Markov model.

**Usage**

```r
mxExpectationHiddenMarkov(components, initial="initial", transition=NULL, 
... , verbose=0L, scale=c('softmax','sum'))
```

**Arguments**

- `components` A character vector of model names.
- `initial` The name of the matrix or algebra column that specifies the initial probabilities.
- `transition` The name of the matrix or algebra that specifies the left stochastic transition probabilities.
- `...` Not used. Forces remaining arguments to be specified by name.
- `verbose` the level of runtime diagnostics
- `scale` How the probabilities are rescaled. For 'softmax', the coefficient-wise exponential is taken and then each column is divided by its column sum. For 'sum', each column is divided by its column sum.

**Details**

Parameters are estimated in the given scale. To obtain the initial column vector and left stochastic transition matrix in probability units then examine the expectation’s output slot.

Definition variables can be used to assign a separate set of mixture probabilities to each row of data. Definition variables can be used in the initial column vector or in the transition matrix, but not in both at the same time.

Note that, when the transition matrix is omitted, this expectation is the same as `mxExpectationMixture`. `mxGenerateData` is not implemented for this type of expectation.

**Examples**

```r
library(OpenMx)

start_prob <- c(2,4,4)
transition_prob <- matrix(c(.8,.1,.1,
 .3,.6,.1,
 .1,.3,.6), 3, 3)
noise <- .5
```
# simulate a trajectory
state <- sample.int(3, 1, prob=transition_prob %*% start_prob)
trail <- c(state)
for (rep in 1:500) {
  state <- sample.int(3, 1, prob=transition_prob[,state])
  trail <- c(trail, state)
}
# add noise
trailN <- sapply(trail, function(v) rnorm(1, mean=v, sd=sqrt(noise)))
classes <- list()
for (cl in 1:3) {
  classes[[cl]] <- mxModel(paste0("cl", cl), type="RAM",
    manifestVars=c("ob"),
    mxPath("one", "ob", value=cl, free=FALSE),
    mxPath("ob", arrows=2, value=noise, free=FALSE),
    mxFitFunctionML(vector=TRUE))
}
m1 <-
  mxModel("hmm", classes,
    mxData(data.frame(ob=trailN), "raw"),
    mxMatrix(nrow=3, ncol=1,
      labels=paste0('i',1:3), name="initial"),
    mxMatrix(nrow=length(classes), ncol=length(classes),
      labels=paste0('t', 1:(length(classes) * length(classes))),
      name="transition"),
    mxExpectationHiddenMarkov(
      components=sapply(classes, function(m) m$name),
      initial="initial",
      transition="transition", scale="softmax"),
    mxFitFunctionML())
m1$transition$free[1:(length(classes)-1), 1:length(classes)] <- TRUE
m1 <- mxRun(m1)
summary(m1)
print(m1$expectation$output)

mxExpectationLISREL Create MxExpectationLISREL Object

Description

This function creates a new MxExpectationLISREL object.
Usage

mxExpectationLISREL(LX=NA, LY=NA, BE=NA, GA=NA, PH=NA, PS=NA, TD=NA, TE=NA, TH=NA, TX = NA, TY = NA, KA = NA, AL = NA, dimnames = NA, thresholds = NA, threshnames = dimnames)

Arguments

LX An optional character string indicating the name of the 'LX' matrix.
LY An optional character string indicating the name of the 'LY' matrix.
BE An optional character string indicating the name of the 'BE' matrix.
GA An optional character string indicating the name of the 'GA' matrix.
PH An optional character string indicating the name of the 'PH' matrix.
PS An optional character string indicating the name of the 'PS' matrix.
TD An optional character string indicating the name of the 'TD' matrix.
TE An optional character string indicating the name of the 'TE' matrix.
TH An optional character string indicating the name of the 'TH' matrix.
TX An optional character string indicating the name of the 'TX' matrix.
TY An optional character string indicating the name of the 'TY' matrix.
KA An optional character string indicating the name of the 'KA' matrix.
AL An optional character string indicating the name of the 'AL' matrix.
dimnames An optional character vector that is currently ignored
thresholds An optional character string indicating the name of the thresholds matrix.
threshnames An optional character vector to be assigned to the column names of the thresholds matrix.

details

Expectation functions define the way that model expectations are calculated. The mxExpectationLISREL calculates the expected covariance and means of a given MxData object given a LISREL model. This model is defined by LInear Structual RELations (LISREL; Jöreskog & Sörbom, 1982, 1996). Arguments 'LX' through 'AL' must refer to MxMatrix objects with the associated properties of their respective matrices in the LISREL modeling approach.

The full LISREL specification has 13 matrices and is sometimes called the extended LISREL model. It is defined by the following equations.

\[ \eta = \alpha + B\eta + \Gamma \xi + \zeta \]
\[ y = \tau_y + \Lambda_y \eta + \epsilon \]
\[ x = \tau_x + \Lambda_x \xi + \delta \]

The table below is provided as a quick reference to the numerous matrices in LISREL models. Note that NX is the number of manifest exogenous (independent) variables, the number of Xs. NY is the number of manifest endogenous (dependent) variables, the number of Ys. NK is the number of latent exogenous variables, the number of Ksis or Xis. NE is the number of latent endogenous variables, the number of etas.
From the extended LISREL model, several submodels can be defined. Subtypes of the LISREL model are defined by setting some of the arguments of the LISREL expectation function to NA. Note that because the default values of each LISREL matrix is NA, setting a matrix to NA can be accomplished by simply not giving it any other value.

The first submodel is the LISREL model without means.

$$
\begin{align*}
\eta &= B \eta + \Gamma \xi + \zeta \\
y &= \Lambda_y \eta + \epsilon \\
x &= \Lambda_x \xi + \delta
\end{align*}
$$

The LISREL model without means requires 9 matrices: LX, LY, BE, GA, PH, PS, TD, TE, and TH. Hence this LISREL model has TX, TY, KA, and AL as NA. This can be accomplished be leaving these matrices at their default values.

The TX, TY, KA, and AL matrices must be specified if either the mxData type is “cov” or “cor” and a means vector is provided, or if the mxData type is “raw”. Otherwise the TX, TY, KA, and AL matrices are ignored and the model without means is estimated.

A second submodel involves only endogenous variables.

$$
\begin{align*}
\eta &= B \eta + \zeta \\
y &= \Lambda_y \eta + \epsilon
\end{align*}
$$

The endogenous-only LISREL model requires 4 matrices: LY, BE, PS, and TE. The LX, GA, PH, TD, and TH must be NA in this case. However, means can also be specified, allowing TY and AL if the data are raw or if observed means are provided.

Another submodel involves only exogenous variables.

$$
\begin{align*}
x &= \Lambda_x \xi + \delta
\end{align*}
$$
The exogenous-model model requires 3 matrices: LX, PH, and TD. The LY, BE, GA, PS, TE, and TH matrices must be NA. However, means can also be specified, allowing TX and KA if the data are raw or if observed means are provided.

The model that is run depends on the matrices that are not NA. If all 9 matrices are not NA, then the full model is run. If only the 4 endogenous matrices are not NA, then the endogenous-only model is run. If only the 3 exogenous matrices are not NA, then the exogenous-only model is run. If some endogenous and exogenous matrices are not NA, but not all of them, then appropriate errors are thrown. Means are included in the model whenever their matrices are provided.

The MxMatrix objects included as arguments may be of any type, but should have the properties described above. The mxExpectationLISREL will not return an error for incorrect specification, but incorrect specification will likely lead to estimation problems or errors in the mxRun function.

Like the mxExpectationRAM, the mxExpectationLISREL evaluates with respect to an MxData object. The MxData object need not be referenced in the mxExpectationLISREL function, but must be included in the MxModel object. mxExpectationLISREL requires that the ‘type’ argument in the associated MxData object be equal to 'cov', 'cor', or 'raw'.

To evaluate, place mxExpectationLISREL objects, the mxData object for which the expected covariance approximates, referenced MxAlgebra and MxMatrix objects, and optional MxBounds and MxConstraint objects in an MxModel object. This model may then be evaluated using the mxRun function. The results of the optimization can be found in the ‘output’ slot of the resulting model, and may be obtained using the mxEval function.

Value

Returns a new MxExpectationLISREL object. One and only one MxExpectationLISREL object can be included with models using one and only one fit function object (e.g., MxFitFunctionML) and with referenced MxAlgebra, MxData and MxMatrix objects.

### mxExpectationMixture

**Mixture expectation**

#### Description

Used in conjunction with `mxFitFunctionML`, this expectation can express a mixture model.

#### Usage

```r
mxExpectationMixture(components, weights="weights",
...,
verbose=0L, scale=c("softmax","sum"))
```

#### Arguments

- `components` A character vector of model names.
- `weights` The name of the matrix or algebra column that specifies the component weights.
- `...` Not used. Forces remaining arguments to be specified by name.
- `verbose` the level of runtime diagnostics
- `scale` How the probabilities are rescaled. For 'softmax', the coefficient-wise exponential is taken and then each column is divided by its column sum. For 'sum', each column is divided by its column sum.

#### Details

Parameters are estimated in the given scale. To obtain the weights column vector, examine the expectation’s output slot.

An extension of this expectation to a Hidden Markov model is available with `mxExpectationHiddenMarkov`. `mxGenerateData` is not implemented for this type of expectation.
Examples

```r
library(OpenMx)

set.seed(1)

trail <- c(rep(1,480), rep(2,520))
trailN <- sapply(trail, function(v) rnorm(1, mean=v))

classes <- list()

for (cl in 1:2) {
  classes[[cl]] <- mxModel(paste0("class", cl), type="RAM",
                            manifestVars=c("ob"),
                            mxPath("one", "ob", value=cl, free=FALSE),
                            mxPath("ob", arrows=2, value=1, free=FALSE),
                            mxFitFunctionML(vector=TRUE))
}

mix1 <- mxModel(
  "mix1", classes,
  mxData(data.frame(ob=trailN), "raw"),
  mxMatrix(values=1, nrow=1, ncol=2, free=c(FALSE,TRUE), name="weights"),
  mxExpectationMixture(paste0("class",1:2), scale="softmax"),
  mxFitFunctionML())

mix1Fit <- mxRun(mix1)
```

mxExpectationNormal

Create MxExpectationNormal Object

Description

This function creates an MxExpectationNormal object.

Usage

```r
mxExpectationNormal(covariance, means, dimnames = NA, thresholds = NA,
                     threshnames = dimnames)
```

Arguments

- `covariance`: A character string indicating the name of the expected covariance algebra.
- `means`: A character string indicating the name of the expected means algebra.
- `dimnames`: An optional character vector to be assigned to the dimnames of the covariance and means algebras.
- `thresholds`: An optional character string indicating the name of the thresholds matrix.
- `threshnames`: An optional character vector to be assigned to the column names of the thresholds matrix.
Details
Expectation functions define the way that model expectations are calculated. The `mxExpectationNormal` function uses the algebra defined by the 'covariance' and 'means' arguments to define the expected covariance and means under the assumption of multivariate normality. The 'covariance' argument takes an MxAlgebra object, which defines the expected covariance of an associated MxData object. The 'means' argument takes an MxAlgebra object, which defines the expected means of an associated MxData object. The 'dimnames' arguments takes an optional character vector. If this argument is not a single NA, then this vector is used to assign the dimnames of the means vector as well as the row and columns dimnames of the covariance matrix.

thresholds: The name of the thresholds matrix. When needed (for modelling ordinal data), this matrix should be created using mxMatrix(). The thresholds matrix must have as many columns as there are ordinal variables in the model, and number of rows equal to one fewer than the maximum number of levels found in the ordinal variables. The starting values of this matrix must also be set to reasonable values. Fill each column with a set of ordered start thresholds, one for each level of this column’s factor levels minus 1. These thresholds may be free if you wish them to be estimated, or fixed. The unused rows in each column, if any, can be set to any value including NA.

threshnames: A character vector consisting of the variables in the thresholds matrix, i.e., the names of ordinal variables in a model. This is necessary for OpenMx to map the thresholds matrix columns onto the variables in your data. If you set the dimnames of the columns in the thresholds matrix then threshnames is not needed.

Usage Notes: dimnames must be supplied where the matrices referenced by the covariance and means algebras are not themselves labeled. Failure to do so leads to an error noting that the covariance or means matrix associated with the FIML objective does not contain dimnames.

`mxExpectationNormal` evaluates with respect to an MxData object. The MxData object need not be referenced in the `mxExpectationNormal` function, but must be included in the MxModel object. When the 'type' argument in the associated MxData object is equal to 'raw', missing values are permitted in the associated MxData object.

To evaluate, place an `mxExpectationNormal` object, the MxData object for which the expected covariance approximates, referenced MxAlgebra and MxMatrix objects, optional MxBounds or MxConstraint objects, and an mxFitFunction such as mxFitFunctionML in an MxModel object. This model may then be evaluated using the mxRun function.

The results of the optimization can be reported using the summary function, or accessed directly in the 'output' slot of the resulting model (i.e., modelName$output). Components of the output may be referenced using the Extract functionality.

Value
Returns an MxExpectationNormal object.

**mxExpectationRAM**  
*Create an MxExpectationRAM Object*

**Description**

This function creates an MxExpectationRAM object.
mxExpectationRAM

Usage

mxExpectationRAM(A="A", S="S", F="F", M = NA, dimnames = NA, thresholds = NA, threshnames = dimnames, ..., between=NULL, verbose=0L)

Arguments

A A character string indicating the name of the 'A' matrix.
S A character string indicating the name of the 'S' matrix.
F A character string indicating the name of the 'F' matrix.
M An optional character string indicating the name of the 'M' matrix.
dimnames An optional character vector to be assigned to the column names of the 'F' and 'M' matrices.
thresholds An optional character string indicating the name of the thresholds matrix.
threshnames An optional character vector to be assigned to the column names of the thresholds matrix.
... Not used. Forces remaining arguments to be specified by name.
between A character vector of matrices that specify cross model relationships.
verbose integer. Level of runtime diagnostic output.

Details

Expectation functions define the way that model expectations are calculated. The mxExpectationRAM calculates the expected covariance and means of a given MxData object given a RAM model. This model is defined by reticular action modeling (McArdle and McDonald, 1984). The 'A', 'S', and 'F' arguments must refer to MxMatrix objects with the associated properties of the A, S, and F matrices in the RAM modeling approach.

The 'dimnames' arguments takes an optional character vector. If this argument is not a single NA, then this vector be assigned to be the column names of the 'F' matrix and optionally to the 'M' matrix, if the 'M' matrix exists.

The 'A' argument refers to the A or asymmetric matrix in the RAM approach. This matrix consists of all of the asymmetric paths (one-headed arrows) in the model. A free parameter in any row and column describes a regression of the variable represented by that row regressed on the variable represented in that column.

The 'S' argument refers to the S or symmetric matrix in the RAM approach, and as such must be square. This matrix consists of all of the symmetric paths (two-headed arrows) in the model. A free parameter in any row and column describes a covariance between the variable represented by that row and the variable represented by that column. Variances are covariances between any variable at itself, which occur on the diagonal of the specified matrix.

The 'F' argument refers to the F or filter matrix in the RAM approach. If no latent variables are included in the model (i.e., the A and S matrices are of both of the same dimension as the data matrix), then the 'F' should refer to an identity matrix. If latent variables are included (i.e., the A and S matrices are not of the same dimension as the data matrix), then the 'F' argument should consist of a horizontal adhesion of an identity matrix and a matrix of zeros.
The 'M' argument refers to the M or means matrix in the RAM approach. It is a 1 x n matrix, where n is the number of manifest variables + the number of latent variables. The M matrix must be specified if either the mxData type is "cov" or "cor" and a means vector is provided, or if the mxData type is "raw". Otherwise the M matrix is ignored.

The MxMatrix objects included as arguments may be of any type, but should have the properties described above. The mxExpectationRAM will not return an error for incorrect specification, but incorrect specification will likely lead to estimation problems or errors in the mxRun function.

mxExpectationRAM evaluates with respect to an MxData object. The MxData object need not be referenced in the mxExpectationRAM function, but must be included in the MxModel object.

To evaluate, place mxExpectationRAM objects, the mxData object for which the expected covariance approximates, referenced MxAlgebra and MxMatrix objects, and optional MxBounds and MxConstraint objects in an MxModel object. This model may then be evaluated using the mxRun function. The results of the optimization can be found in the 'output' slot of the resulting model, and may be obtained using the mxEval function.

Value

Returns a new MxExpectationRAM object. mxExpectationRAM objects should be included with models with referenced MxAlgebra, MxData and MxMatrix objects.

Examples

# Create and fit a model using mxMatrix, mxAlgebra, # mxExpectationNormal, and mxFitFunctionML

library(OpenMx)

# Simulate some data

x=rnorm(1000, mean=0, sd=1)
y= 0.5*x + rnorm(1000, mean=0, sd=1)
tmpFrame <- data.frame(x, y)
tmpNames <- names(tmpFrame)

# Define the matrices

matrixS <- mxMatrix(type = "Full", nrow = 2, ncol = 2, values=c(1,0,0,1),
  free=c(TRUE,FALSE,FALSE,TRUE), labels=c("Vx", NA, NA, "Vy"),
  name = "S")
matrixA <- mxMatrix(type = "Full", nrow = 2, ncol = 2, values=c(0,1,0,0),
  free=c(FALSE,TRUE,FALSE,FALSE), labels=c(NA, "b", NA, NA),
  name = "A")
mxExpectationStateSpace

Create an MxExpectationStateSpace Object

Description

This function creates a new MxExpectationStateSpace object.

Usage

mxExpectationStateSpace(A, B, C, D, Q, R, x0, P0, u,
                          dimnames = NA, thresholds = NA, threshnames = dimnames,
                          ..., t = NA, scores=FALSE)

Arguments

A  A character string indicating the name of the 'A' matrix.
B  A character string indicating the name of the 'B' matrix.
C  A character string indicating the name of the 'C' matrix.
D  A character string indicating the name of the 'D' matrix.
Q  A character string indicating the name of the 'Q' matrix.
R  A character string indicating the name of the 'R' matrix.
x0 A character string indicating the name of the 'x0' matrix.
mxExpectationStateSpace

P0  A character string indicating the name of the 'P0' matrix.
u  A character string indicating the name of the 'u' matrix.
dimnames  An optional character vector to be assigned to the row names of the 'C' matrix.
thresholds  Not Yet Implemented. An optional character string indicating the name of the thresholds matrix.
threshnames  Not Yet Implemented. An optional character vector to be assigned to the column names of the thresholds matrix.
...  Unused. Requires further arguments to be named.
t  Not to be used
scores  Not to be used

Details

Expectation functions define the way that model expectations are calculated. When used in conjunction with the mxFitFunctionML, the mxExpectationStateSpace uses maximum likelihood prediction error decomposition (PED) to obtain estimates of free parameters in a model of the raw MxData object. State space expectations treat the raw data as a multivariate time series of equally spaced times with each row corresponding to a single occasion. This is not a model of the block Toeplitz lagged autocovariance matrix. State space expectations implement a classical Kalman filter to produce expectations.

The hybrid Kalman filter (combination of classical Kalman and Kalman-Bucy filters) for continuous latent time with discrete observations is implemented and is available as mxExpectationStateSpace-ContinuousTime. The following alternative filters are not yet implemented: square root Kalman filter (in Cholesky or singular value decomposition form), extended Kalman filter for linear approximations to nonlinear state space models, unscented Kalman filter for highly nonlinear state space models, and Rauch-Tung-Striebel smoother for updating forecast state estimates after a complete forward pass through the data has been made.

Missing data handling is implemented in the same fashion as full information maximum likelihood for partially missing rows of data. Additionally, completely missing rows of data are handled by only using the prediction step from the Kalman filter and omitting the update step.

This model uses notation for the model matrices commonly found in engineering and control theory. The 'A', 'B', 'C', 'D', 'Q', 'R', 'x0', and 'P0' arguments must be the names of MxMatrix or MxAlgebra objects with the associated properties of the A, B, C, D, Q, R, x0, and P0 matrices in the state space modeling approach.

The state space expectation is defined by the following model equations.

\[ x_t = Ax_{t-1} + Bu_t + q_t \]
\[ y_t = Cx_t + Du_t + r_t \]

with \( q_t \) and \( r_t \) both independently and identically distributed random Gaussian (normal) variables with mean zero and covariance matrices \( Q \) and \( R \), respectively.

The first equation is called the state equation. It describes how the latent states change over time. Also, the state equation in state space modeling is directly analogous to the structural model in LISREL structural equation modeling.
The second equation is called the output equation. It describes how the latent states relate to the observed states at a single point in time. The output equation shows how the observed output is produced by the latent states. Also, the output equation in state space modeling is directly analogous to the measurement model in LISREL structural equation modeling.

Note that the covariates, $u$, have "instantaneous" effects on both the state and output equations. If lagged effects are desired, then the user must create a lagged covariate by shifting their observed variable to the desired lag.

The state and output equations, together with some minimal assumptions and the Kalman filter, imply a new expected covariance matrix and means vector for every row of data. The expected covariance matrix of row $t$ is

$$S_t = C(A P_{t-1} A^T + Q)C^T + R$$

The expected means vector of row $t$ is

$$\hat{y}_t = C x_t + D u_t$$

The 'dimnames' arguments takes an optional character vector.

The 'A' argument refers to the $A$ matrix in the State Space approach. This matrix consists of time regressive coefficients from the latent variable in column $j$ at time $t - 1$ to the latent variable in row $i$ at time $t$. Entries in the diagonal are autoregressive coefficients. Entries in the off-diagonal are cross-lagged regressive coefficients. If the $A$ and $B$ matrices are zero matrices, then the state space model reduces to a factor analysis. The $A$ matrix is sometimes called the state-transition model.

The 'B' argument refers to the $B$ matrix in the State Space approach. This matrix consists of regressive coefficients from the input (manifest covariate) variable $j$ at time $t$ to the latent variable in row $i$ at time $t$. Note that the covariate effect is contemporaneous: the covariate at time $t$ has influence on the latent state also at time $t$. A lagged effect can be created by lagged the observed variable. The $B$ matrix is sometimes called the control-input model.

The 'C' argument refers to the $C$ matrix in the State Space approach. This matrix consists of contemporaneous regression coefficients from the latent variable in column $j$ to the observed variable in row $i$. This matrix is directly analogous to the factor loadings matrix in LISREL and Mplus models. The $C$ matrix is sometimes called the observation model.

The 'D' argument refers to the $D$ matrix in the State Space approach. This matrix consists of contemporaneous regressive coefficients from the input (manifest covariate) variable $j$ to the observed variable in row $i$. The $D$ matrix is sometimes called the feedthrough or feedforward matrix.

The 'Q' argument refers to the $Q$ matrix in the State Space approach. This matrix consists of residual covariances among the latent variables. This matrix must be symmetric. As a special case, it is often diagonal. The $Q$ matrix is the covariance of the process noise. Just as in factor analysis and general structural equation modeling, the scale of the latent variables is usually set by fixing some factor loadings in the $C$ matrix, or fixing some factor variances in the $Q$ matrix.

The 'R' argument refers to the $R$ matrix in the State Space approach. This matrix consists of residual covariances among the observed (manifest) variables. This matrix must be symmetric As a special case, it is often diagonal. The $R$ matrix is the covariance of the observation noise.

The 'x0' argument refers to the $x_0$ matrix in the State Space approach. This matrix consists of the column vector of the initial values for the latent variables. The state space expectation uses the $x_0$
matrix as the starting point to recursively estimate the latent variables’ values at each time. These starting values can be difficult to pick, however, for sufficiently long time series they often do not greatly impact the estimation.

The 'P0' argument refers to the $P_0$ matrix in the State Space approach. This matrix consists of the initial values of the covariances of the error in the initial latent variable estimates given in $x_0$. That is, the $P_0$ matrix gives the covariance of $x_0 - x_{true}$ where $x_{true}$ is the vector of true initial values. $P_0$ is a measure of the accuracy of the initial latent state estimates. The Kalman filter uses this initial covariance to recursively generated a new covariance for each time point based on the previous time point. The Kalman filter updates this covariance so that it is as small as possible (minimum trace). Similar to the $x_0$ matrix, these starting values are often difficult to choose.

The 'u' argument refers to the $u$ matrix in the State Space approach. This matrix consists of the inputs or manifest covariates of the state space expectation. The $u$ matrix must be a column vector with the same number of rows as the $B$ and $D$ matrices have columns. If no inputs are desired, $u$ can be a zero matrix. If time-varying inputs are desired, then they should be included as columns in the MxData object and referred to in the labels of the $u$ matrix as definition variables. There is an example of this below.

The MxMatrix objects included as arguments may be of any type, but should have the properties described above. The mxExpectationStateSpace will not return an error for incorrect specification, but incorrect specification will likely lead to estimation problems or errors in the mxRun function.

mxExpectationStateSpace evaluates with respect to an MxData object. The MxData object need not be referenced in the mxExpectationStateSpace function, but must be included in the MxModel object. mxExpectationStateSpace requires that the 'type' argument in the associated MxData object be equal to 'raw'. Neighboring rows of the MxData object are treated as adjacent, equidistant time points increasing from the first to the last row.

To evaluate, place mxExpectationStateSpace objects, the mxData object for which the expected covariance approximates, referenced MxAlgebra and MxMatrix objects, and optional MxBounds and MxConstraint objects in an MxModel object. This model may then be evaluated using the mxRun function. The results of the optimization can be found in the 'output' slot of the resulting model, and may be obtained using the mxEval function.

Value

Returns a new MxExpectationStateSpace object. mxExpectationStateSpace objects should be included with models with referenced MxAlgebra, MxData and MxMatrix objects.

                   mxFitFunctionML())
ssRun <- mxRun(ssModel)
summary(ssRun)
# Note the freely estimated Autoregressive parameter (A matrix)
# and the freely estimated Control-Input parameter (B matrix)
# are both near zero as they should be for the independent rows of data
# from the factor model that does not have inputs, covariates,
# or exogenous variables.

mxExpectationStateSpaceContinuousTime

Create an MxExpectationStateSpace Object

Description

This function creates a new MxExpectationStateSpace object.

Usage

mxExpectationStateSpaceContinuousTime(A, B, C, D, Q, R, x0, P0, u, t = NA,
    dimnames = NA, thresholds = NA, threshnames = dimnames,
    ..., scores=FALSE)
mxExpectationSSCT(A, B, C, D, Q, R, x0, P0, u, t = NA,
    dimnames = NA, thresholds = NA, threshnames = dimnames,
    ..., scores=FALSE)

Arguments

A       A character string indicating the name of the 'A' matrix.
B       A character string indicating the name of the 'B' matrix.
C       A character string indicating the name of the 'C' matrix.
D       A character string indicating the name of the 'D' matrix.
Q       A character string indicating the name of the 'Q' matrix.
R       A character string indicating the name of the 'R' matrix.
x0      A character string indicating the name of the 'x0' matrix.
P0      A character string indicating the name of the 'P0' matrix.
u      A character string indicating the name of the 'u' matrix.
t      A character string indicating the name of the 't' matrix.
dimnames An optional character vector to be assigned to the row names of the 'C' matrix.
thresholds Not Yet Implemented. An optional character string indicating the name of the thresholds matrix.
threshnames Not Yet Implemented. An optional character vector to be assigned to the column names of the thresholds matrix.
...        Unused. Requires further arguments to be named.
scores     Not to be used
The \texttt{mxExpectationStateSpaceContinuousTime} and \texttt{mxExpectationSSCT} functions are identical. The latter is simply an abbreviated name. When using the former, tab completion is strongly encouraged to save tedious typing. Both of these functions are wrappers for the \texttt{mxExpectationStateSpace} function, which could be used for both discrete and continuous time modeling. However, there is a strong possibility of misunderstanding the model parameters when switching between discrete time and continuous time. The expectation matrices have the same names, but mean importantly different things so caution is warranted. The best practice is to use \texttt{mxExpectationStateSpace} for discrete time models, and \texttt{mxExpectationStateSpaceContinuousTime} for continuous time models.

Expectation functions define the way that model expectations are calculated. That is to say, expectation functions define how a set of model matrices get turned into expectations for the data. When used in conjunction with the \texttt{mxFitFunctionML}, the \texttt{mxExpectationStateSpace} uses maximum likelihood prediction error decomposition (PED) to obtain estimates of free parameters in a model of the raw \texttt{MxData} object. Continuous time state space expectations treat the raw data as a multivariate time series of possibly unevenly spaced times with each row corresponding to a single occasion. Continuous time state space expectations implement a hybrid Kalman filter to produce expectations. The hybrid Kalman filter uses a Kalman-Bucy filter for the prediction step and the classical Kalman filter for the update step. It is a hybrid between the classical Kalman filter used for the discrete (but possibly unequally spaced) measurement occasions and the continuous time Kalman-Bucy filter for latent variable predictions.

Missing data handling is implemented in the same fashion as full information maximum likelihood for partially missing rows of data. Additionally, completely missing rows of data are handled by only using the prediction step from the Kalman-Bucy filter and omitting the update step.

This model uses notation for the model matrices commonly found in engineering and control theory. The \texttt{’A’}, \texttt{’B’}, \texttt{’C’}, \texttt{’D’}, \texttt{’Q’}, \texttt{’R’}, \texttt{’x0’}, and \texttt{’P0’} arguments must be the names of \texttt{MxMatrix} or \texttt{MxAlgebra} objects with the associated properties of the A, B, C, D, Q, R, x0, and P0 matrices in the state space modeling approach. The \texttt{’t’} matrix must be a 1x1 matrix using definition variables that gives the times at which measurements occurred.

The state space expectation is defined by the following model equations.

\[
\frac{d}{dt} x(t) = Ax(t) + Bu(t) + q(t) \\
y_t = Cx_t + Du_t + r_t
\]

with \(q(t)\) and \(r_t\) both independently and identically distributed random Gaussian (normal) variables with mean zero and covariance matrices \(Q\) and \(R\), respectively. Subscripts or square brackets indicate discrete indices; parentheses indicate continuous indices. The derivative of \(x(t)\) with respect to \(t\) is \(\frac{d}{dt} x(t)\).

The first equation is called the state equation. It describes how the latent states change over time with a first-order linear differential equation. Unlike some other programs, we do not require that the continuous time \(A\) matrix has an inverse. This allows zero dynamics (i.e. no growth models) and many other important kinds of processes.

The second equation is called the output equation. It describes how the latent states relate to the observed states at a single point in time. The output equation shows how the observed output is
produced by the latent states. Also, the output equation in state space modeling is directly analogous to the measurement model in LISREL structural equation modeling.

Note that the covariates, \( u \), have "instantaneous" effects on both the state and output equations. If lagged effects are desired, then the user must create a lagged covariate by shifting their observed variable to the desired lag.

The state and output equations, together with some minimal assumptions and the Kalman filter, imply a new expected covariance matrix and means vector for every row of data. The expected covariance matrix of row \( t \) is

\[
S_t = C(AP_{t-1}A^T + Q)C^T + R
\]

The expected means vector of row \( t \) is

\[
\hat{y}_t = Cx_t + Du_t
\]

The 'dimnames' arguments takes an optional character vector.

The 'A' argument refers to the \( A \) matrix in the State Space approach. This matrix gives the dynamics. Entries in the diagonal give the strength of the influence of a variable’s position on its slope. Entries in the off-diagonal give the coupling strength from one variable to another. The \( A \) matrix is sometimes called the state-transition model.

The 'B' argument refers to the \( B \) matrix in the State Space approach. This matrix consists of exogenous forces that influence the dynamics. Note that the covariate effect is contemporaneous: the covariate at time \( t \) has influence on the slope of the latent state also at time \( t \). A lagged effect can be created by lagged the observed variable. The \( B \) matrix is sometimes called the control-input model.

The 'C' argument refers to the \( C \) matrix in the State Space approach. This matrix consists of contemporaneous regression coefficients from the latent variable in column \( j \) to the observed variable in row \( i \). This matrix is directly analogous to the factor loadings matrix in LISREL and Mplus models. The \( C \) matrix is sometimes called the observation model.

The 'D' argument refers to the \( D \) matrix in the State Space approach. This matrix consists of contemporaneous regressive coefficients from the input (manifest covariate) variable \( j \) to the observed variable in row \( i \). The \( D \) matrix is sometimes called the feedthrough or feedforward matrix.

The 'Q' argument refers to the \( Q \) matrix in the State Space approach. This matrix gives the covariance of the dynamic noise. The dynamic noise can be thought of as unmeasured covariate inputs active at all times. This matrix must be symmetric, diagonal, or zero. As a special case, it is often diagonal. The \( Q \) matrix is the covariance of the process noise. Just as in factor analysis and general structural equation modeling, the scale of the latent variables is usually set by fixing some factor loadings in the \( C \) matrix, or fixing some factor variances in the \( Q \) matrix.

The 'R' argument refers to the \( R \) matrix in the State Space approach. This matrix consists of residual covariances among the observed (manifest) variables. This matrix must be symmetric. As a special case, it is often diagonal. The \( R \) matrix is the covariance of the observation noise.

The 'x0' argument refers to the \( x_0 \) matrix in the State Space approach. This matrix consists of the column vector of the initial values for the latent variables. The state space expectation uses the \( x_0 \) matrix as the starting point to recursively estimate the latent variables’ values at each time. These
starting values can be difficult to pick, however, for sufficiently long time series they often do not
greatly impact the estimation.

The 'P0' argument refers to the $P_0$ matrix in the State Space approach. This matrix consists of the
initial values of the covariances of the error in the initial latent variable estimates given in $x_0$. That
is, the $P_0$ matrix gives the covariance of $x_0 - x_{true0}$ where $x_{true0}$ is the vector of true initial
values. $P_0$ is a measure of the accuracy of the initial latent state estimates. The Kalman filter uses
this initial covariance to recursively generated a new covariance for each time point based on the
previous time point. The Kalman filter updates this covariance so that it is as small as possible
(minimum trace). Similar to the $x_0$ matrix, these starting values are often difficult to choose.

The 'u' argument refers to the $u$ matrix in the State Space approach. This matrix consists of the
inputs or manifest covariates of the state space expectation. The $u$ matrix must be a column vector
with the same number of rows as the $B$ and $D$ matrices have columns. If no inputs are desired, $u$
can be a zero matrix. If time-varying inputs are desired, then they should be included as columns in
the MxData object and referred to in the labels of the $u$ matrix as definition variables. There is an
example of this below.

The 't' argument refers to the $t$ matrix in the State Space approach. This matrix should be 1x1 (1 row
and 1 column) and not free. The label for the element of this matrix should be 'data.YourTimeVariable'.
The 'data' part does not change, but 'YourTimeVariable' should be a name in your data set that gives
the times at which measurement happened. The units of time are up to you. Your choice of time
units will influence of the values of the parameters you estimate. Also, recall that the model is given
$x_0$ and $P_0$. These always happen at $t = 0$. So the first row of data happens some amount of time
after zero.

The MxMatrix objects included as arguments may be of any type, but should have the properties
described above. The mxExpectationStateSpace will not return an error for incorrect specification,
but incorrect specification will likely lead to estimation problems or errors in the mxRun function.

mxExpectationStateSpaceContinuousTime evaluates with respect to an MxData object. The Mx-
Data object need not be referenced in the mxExpectationStateSpace function, but must be included
in the MxModel object. mxExpectationStateSpace requires that the 'type' argument in the asso-
ciated MxData object be equal to 'raw'. Neighboring rows of the MxData object are treated as
adjacent, equidistant time points increasing from the first to the last row.

To evaluate, place an mxExpectationStateSpaceContinuousTime object, the mxData object for which
the expected covariance approximates, referenced MxAlgebra and MxMatrix objects, and optional
MxBounds and MxConstraint objects in an MxModel object. This model may then be evaluated
using the mxRun function. The results of the optimization can be found in the 'output' slot of the
resulting model, and may be obtained using the mxEval function.

Value

Returns a new MxExpectationStateSpace object. mxExpectationStateSpace objects should be in-
cluded with models with referenced MxAlgebra, MxData and MxMatrix objects.

mxFactor  Fail-safe Factors

Description
This is a wrapper for the R function factor.
OpenMx requires ordinal data to be ordered. R’s factor function doesn’t enforce this, hence this wrapper exists to throw an error should you accidentally try and run with ordered = FALSE.
Also, the ‘levels’ parameter is optional in R’s factor function. However, relying on the data to specify the data is foolhardy for the following reasons: The factor function will skip levels
missing from the data: Specifying these in levels leaves the list of levels complete. Data will often not explore the min and max level that the user knows are possible. For these reasons this function forces you to write out all possible levels explicitly.

Usage

```
mxFactor(x = character(), levels, labels = levels, 
        exclude = NA, ordered = TRUE, collapse = FALSE)
```

Arguments

- **x**: either a vector of data or a data.frame object.
- **levels**: a mandatory vector of the values that 'x' might have taken.
- **labels**: _either_ an optional vector of labels for the levels, _or_ a character string of length 1.
- **exclude**: a vector of values to be excluded from the set of levels.
- **ordered**: logical flag to determine if the levels should be regarded as ordered (in the order given). Required to be TRUE.
- **collapse**: logical flag to determine if duplicate labels should collapsed into a single level

Details

If ‘x’ is a data.frame, then all of the columns of ‘x’ are converted into ordered factors. If ‘x’ is a data.frame, then ‘levels’ and ‘labels’ may be either a list or a vector. When ‘levels’ is a list, then different levels are assigned to different columns of the constructed data.frame object. When ‘levels’ is a vector, then the same levels are assigned to all the columns of the data.frame object. The function will throw an error if ‘ordered’ is not TRUE or if ‘levels’ is missing. See factor for more information on creating ordered factors.

The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.

Examples

```
myVar <- c("s", "t", "a", "t", "i", "s", "t", "i", "c", "s")
ff <- mxFactor(myVar, levels=letters)
# Note: letters is a built in list of all lowercase letters of the alphabet
ff
# [1] s t a t i s t i c s
# Levels: a < b < c < d < e < f < g < h < i < j < k < l < m < n < o < p < q <
# r < s < t < u < v < w < x < y < z
as.integer(ff) # the internal codes
factor(ff)     # NOTE: drops the levels that do not occur.  
                # mxFactor prevents you doing this unintentionally.

# This example works on a dataframe
```
foo <- data.frame(x=c(1:3), y=c(4:6), z=c(7:9))

# Applies one set of levels to all three columns
mxFactor(foo, c(1:9))

# Apply unique sets of levels to each variable
mxFactor(foo, list(c(1:3), c(4:6), c(7:9)))

mxFactor(foo, c(1:9), labels=c(1,1,1,2,2,2,3,3,3), collapse=TRUE)

---

**mxFactorScores**

*Estimate factor scores and standard errors*

**Description**

This function creates the factor scores and their standard errors under different methods for an MxModel object that has either a RAM or LISREL expectation.

**Usage**

```r
mxFactorScores(model, type=c('ML', 'WeightedML', 'Regression'), minManifests=as.integer(NA))
```

**Arguments**

- `model`: An MxModel object with either an MxExpectationLISREL or MxExpectationRAM
- `type`: The type of factor scores to compute
- `minManifests`: Set scores to NA when there are less than minManifests non-NA manifest variables

**Details**

This is a helper function to compute or estimate factor scores along with their standard errors. The two maximum likelihood methods create a new model for each data row. They then estimate the factor scores as free parameters in a model with a single data row. For 'ML', the conditional likelihood of the data given the factor scores is optimized:

\[ L(D|F) \]

. For 'WeightedML', the joint likelihood of the data and the factor scores is optimized:

\[ L(D, F) = L(D|F)L(F) \]

. The WeightedML scores are akin to the empirical Bayes random effects estimates from mixed effects modeling. They display the same kind of shrinkage as random effects estimates, and for the same reason: they account for the latent variable distribution in their estimation.
In many cases, especially for ordinal data or missing data, the weighted ML scores are to be preferred over alternatives (Estabrook & Neale, 2013). For example, when using ordinal data, a person whose observations are all in the highest ordinal category theoretically has an 'ML' factor score of positive infinity. A similar situation arises for a person whose observations are all in the lowest ordinal category: their 'ML' factor score is theoretically negative infinity. Weighted ML factor scores in these cases remain reasonable.

For type='Regression', with LISREL expectation, factor scores are computed based on a simple formula. This formula is equivalent to the formula for the Kalman updated scores in a state space model with zero dynamics (Priestly & Subba Rao, 1975). Thus, to compute the regression factor scores, the appropriate state space model is set-up and the mxKalmanScores function is used to produce the factor scores and their standard errors. With RAM expectation, factor scores are predicted from the non-missing manifest variables for each row of the raw data, using a general linear prediction formula analytically equivalent to that used with LISREL expectation. The standard errors for regression-predicted RAM factor scores are the square roots of the indeterminate variances of the latent variables, given the data row’s missing-data pattern and the values of any relevant definition variables. The RAM and LISREL methods for computing regression factor scores with their standard errors are analytically identical. They produce the same score and standard error estimates.

If you have missing data then you must specify minManifests. This option will set scores to NA when there are too few items to make an accurate score estimate. If you are using the scores as point estimates without considering the standard error then you should set minManifests as high as you can tolerate. This will increase the amount of missing data but scores will be more accurate. If you are carefully considering the standard errors of the scores then you can set minManifests to 0. When set to 0, all NA rows are scored to the prior distribution.

Note that for compatibility with factanal, type='regression' is also acceptable.

Value

An array with dimensions (Number of Rows of Data, Number of Latent Variables, 2). The third dimension has the scores in the first slot and the standard errors in the second slot. The rows are in the order of the unsorted data. Multigroup models are an exception, in that the returned value is instead a list of such arrays, containing one per group.

mxFIMLObjective  DEPRECATED: Create MxFIMLObjective Object

Description

WARNING: Objective functions have been deprecated as of OpenMx 2.0.
Please use mxExpectationNormal() and mxFitFunctionML() instead. As a temporary workaround,
mxFIMLObjective returns a list containing an MxExpectationNormal object and an MxFitFunctionML object.
All occurrences of
mxFIMLObjective(covariance, means, dimnames = NA, thresholds = NA, vector = FALSE, threshnames = dimnames)
Should be changed to
mxExpectationNormal(covariance, means, dimnames = NA, thresholds = NA, threshnames = dimnames) mxFitFunctionML(vector = FALSE)

Arguments

covariance  A character string indicating the name of the expected covariance algebra.
means  A character string indicating the name of the expected means algebra.
mxFIMLObjective

dimnames: An optional character vector to be assigned to the dimnames of the covariance and means algebras.

thresholds: An optional character string indicating the name of the thresholds matrix.

vector: A logical value indicating whether the objective function result is the likelihood vector.

threshnames: An optional character vector to be assigned to the column names of the thresholds matrix.

Details

NOTE: THIS DESCRIPTION IS DEPRECATED. Please change to using mxExpectationNormal and mxFitFunctionML as shown in the example below.

Objective functions were functions for which free parameter values are chosen such that the value of the objective function is minimized. The mxFIMLObjective function used full-information maximum likelihood to provide maximum likelihood estimates of free parameters in the algebra defined by the 'covariance' and 'means' arguments. The 'covariance' argument takes an MxAlgebra object, which defines the expected covariance of an associated MxData object. The 'means' argument takes an MxAlgebra object, which defines the expected means of an associated MxData object. The 'dimnames' arguments takes an optional character vector. If this argument is not a single NA, then this vector is used to assign the dimnames of the means vector as well as the row and columns dimnames of the covariance matrix.

The 'vector' argument is either TRUE or FALSE, and determines whether the objective function returns a column vector of the likelihoods, or a single -2*(log likelihood) value.

thresholds: The name of the thresholds matrix. When needed (for modelling ordinal data), this matrix should be created using mxMatrix(). The thresholds matrix must have as many columns as there are ordinal variables in the model, and number of rows equal to one fewer than the maximum number of levels found in the ordinal variables. The starting values of this matrix must also be set to reasonable values. Fill each column with a set of ordered start thresholds, one for each level of this column’s factor levels minus 1. These thresholds may be free if you wish them to be estimated, or fixed. The unused rows in each column, if any, can be set to any value including NA.

threshnames: A character vector consisting of the variables in the thresholds matrix, i.e., the names of ordinal variables in a model. This is necessary for OpenMx to map the thresholds matrix columns onto the variables in your data. If you set the dimnames of the columns in the thresholds matrix then threshnames is not needed.

Usage Notes: dimnames must be supplied where the matrices referenced by the covariance and means algebras are not themselves labeled. Failure to do so leads to an error noting that the covariance or means matrix associated with the FIML objective does not contain dimnames.

mxFIMLObjective evaluates with respect to an MxData object. The MxData object need not be referenced in the mxFIMLObjective function, but must be included in the MxModel object. mxFIMLObjective requires that the 'type' argument in the associated MxData object be equal to 'raw'. Missing values are permitted in the associated MxData object.

To evaluate, place MxFIMLObjective objects, the MxData object for which the expected covariance approximates, referenced MxAlgebra and MxMatrix objects, and optional MxBounds and MxConstraint objects in an MxModel object. This model may then be evaluated using the mxRun function.
The results of the optimization can be reported using the `summary` function, or accessed directly in the 'output' slot of the resulting model (i.e., `modelName$output`). Components of the output may be referenced using the `Extract` functionality.

**Value**

Returns a list containing an `MxExpectationNormal` object and an `MxFitFunctionML` object.

# Define the expectation
expCov <- mxAlgebra(solve(I-A) %*% S %*% t(solve(I-A)), name="expCov")
expFunction <- mxExpectationNormal(covariance="expCov", means="M", dimnames=tmpNames)

# Choose a fit function
fitFunction <- mxFitFunctionML()

# Define the model
tmpModel <- mxModel(model="exampleModel", M, S, A, I, expCov, expFunction, fitFunction,
                     mxData(observed=tmpFrame, type="raw"))

# Fit the model and print a summary
```
tmpModelOut <- mxRun(tmpModel)
summary(tmpModelOut)

## MxFitFunction-class  MxFitFunction

### Description

This is an internal class and should not be used directly.

## mxFitFunctionAlgebra  Create MxFitFunctionAlgebra Object

### Description

`mxFitFunctionAlgebra` returns an `MxFitFunctionAlgebra` object.

### Usage

`mxFitFunctionAlgebra(algebra, numObs = NA, numStats = NA, ..., gradient = NA_character_, hessian = NA_character_, verbose = 0L, units="-2lnL")`

### Arguments

- **algebra**: A character string indicating the name of an `MxAlgebra` or `MxMatrix` object to use for optimization.
- **numObs**: (optional) An adjustment to the total number of observations in the model.
- **numStats**: (optional) An adjustment to the total number of observed statistics in the model.
- **...**: Not used. Forces remaining arguments to be specified by name.
- **gradient**: (optional) A character string indicating the name of an `MxAlgebra` object.
- **hessian**: (optional) A character string indicating the name of an `MxAlgebra` object.
- **verbose**: (optional) An integer to increase the level of runtime log output.
- **units**: (optional) The units of the fit statistic.
Details

If you want to fit a multigroup model, the preferred way is to use `mxFitFunctionMultigroup`.

Fit functions are functions for which free parameter values are chosen such that the value of the objective function is minimized. While the other fit functions in OpenMx require an expectation function for the model, the `mxAlgebraObjective` function uses the referenced `MxAlgebra` or `MxMatrix` object as the function to be minimized.

If a model's fit function is an `mxFitFunctionAlgebra` objective function, then the referenced algebra in the objective function must return a 1 x 1 matrix (when using OpenMx's default optimizer).

There is no restriction on the dimensions of an fit function that is not the primary, or 'topmost', objective function.

To evaluate an algebra fit function, place the following objects in a `MxModel` object: a `mxFitFunctionAlgebra`, `MxAlgebra` and `MxMatrix` entities referenced by the `MxAlgebraObjective`, and optional `MxBounds` and `MxConstraint` objects. This model may then be evaluated using the `mxRun` function. The results of the optimization may be obtained using the `mxEval` function on the name of the `MxAlgebra`, after the model has been run.

First and second derivatives can be provided with the algebra fit function. The dimnames on the gradient and hessian `MxAlgebra`s are matched against names of free variables. Names that do not match are ignored. The fit is assumed to be in deviance units (-2 log likelihood units). If you are working in log likelihood units, the -2 scaling factor is not applied automatically. You have to multiply by -2 yourself.

Value

Returns an `MxFitFunctionAlgebra` object. `MxFitFunctionAlgebra` objects should be included with models with referenced `MxAlgebra` and `MxMatrix` objects.

Examples

```r
# Create and fit a very simple model that adds two numbers using mxFitFunctionAlgebra
library(OpenMx)

# Create a matrix 'A' with no free parameters
A <- mxMatrix('Full', nrow = 1, ncol = 1, values = 1, name = 'A')

# Create an algebra 'B', which defines the expression A + A
```
B <- mxAlgebra(A + A, name = 'B')

# Define the objective function for algebra 'B'
objective <- mxFitFunctionAlgebra('B')

# Place the algebra, its associated matrix and
# its objective function in a model
tmpModel <- mxModel(model="Addition", A, B, objective)

# Evaluate the algebra
tmpModelOut <- mxRun(tmpModel)

# View the results
tmpModelOut$output$minimum

---

mxFitFunctionGREML  Create MxFitFunctionGREML Object

Description

This function creates a new MxFitFunctionGREML object.

Usage

mxFitFunctionGREML(dV=character(0), aug=character(0),
                   augGrad=character(0), augHess=character(0))

Arguments

dV  Vector of character strings; defaults to a character vector of length zero. If a value of non-zero length is provided, it must be a named character vector. This vector's names must be the labels of each free parameter in the model. The vector's elements (i.e., the character strings themselves) must be the names of MxAlgebra or MxMatrix object(s), each of which equals the first partial derivative of the 'V' matrix with respect to the corresponding free parameter.

aug  Character string; defaults to a character vector of length zero. Any elements after the first are ignored. The string should name a 1x1 MxMatrix or an MxAlgebra that evaluates to a 1x1 matrix. The named object will be used as an "augmentation" to the GREML fitfunction--specifically, the [1,1] value of the object named by aug will be added to the GREML fitfunction value at each function evaluation during optimization. The augmentation can be used to regularize estimation with a prior likelihood, or to use penalty functions to approximate constraints.

augGrad  Character string; defaults to a character vector of length zero. Any elements after the first are ignored. The string should name a MxMatrix or an MxAlgebra that evaluates to the gradient of aug with respect to free parameters. The gradient can be either a column or row vector. The free parameters corresponding to the elements of the gradient vector are taken from the names of argument dV, e.g. if
the third name of $dV$ is 'va', then the third element of the gradient vector should be the first partial derivative of the augmentation function with respect to 'va'. Ignored unless both $dV$ and aug have nonzero length.

**augHess**

Character string; defaults to a character vector of length zero. Any elements after the first are ignored. The string should name a MxMatrix or an MxAlgebra that evaluates to the Hessian of aug with respect to free parameters. The free parameters corresponding to each row and column of this matrix are dictated by the names of argument $dV$, in the same manner as for the elements of augGrad. Ignored unless both $dV$ and aug have nonzero length. Providing a nonzero-length value for augHess but not augGrad will result in an error at runtime.

**Details**

Making effective use of arguments $dV$, augGrad, and augHess will usually require a custom mxComputeSequence(). The derivatives of the REML loglikelihood function with respect to parameters can be internally computed from the derivatives of the 'V' matrix supplied via $dV$. These loglikelihood derivatives will be valid as long as (1) the derivatives of 'V' evaluate to symmetric matrices the same size as 'V,' and (2) the model contains no MxConstraints. Internally, the derivatives of the 'V' matrix are assumed to be symmetric, and the elements above their main diagonals are ignored.

Currently, if any derivatives are provided via $dV$, then derivatives must be provided for every free parameter in the MxModel.

Argument aug is intended to allow users to provide penalty functions or prior likelihoods in order to approximate constraints or to regularize optimization. The user is warned that careless use of this augmentation feature may undermine the validity of his/her statistical inferences.

**Value**

Returns a new object of class MxFitFunctionGREML.

**Examples**

```r
  gff <- mxFitFunctionGREML()
  str(gff)
```
Description

`MxFitFunctionGREML` is the fitfunction class for GREML analyses.

Objects from the Class

Objects can be created by calls of the form `mxFitFunctionGREML(dV)`.

Slots

dV: Object of class "MxCharOrNumber". Identifies the `MxAlgebra` or `MxMatrix` object(s) to serve as the derivatives of `V` with respect to free parameters.
dVnames: Vector of character strings; names of the free parameters corresponding to slot dV.
MLfit: Object of class "numeric", equal to the maximum-likelihood fitfunction value (as opposed to the restricted maximum-likelihood value).
numObs: Object of class "integer". Number of observations.
aug: Object of class "MxCharOrNumber". Identifies the `MxAlgebra` or `MxMatrix` object used to "augment" the fitfunction value at each function evaluation during optimization.
augGrad: Object of class "MxCharOrNumber". Identifies the `MxAlgebra` or `MxMatrix` object(s) to serve as the first derivatives of aug with respect to free parameters.
augHess: Object of class "MxCharOrNumber". Identifies the `MxAlgebra` or `MxMatrix` object(s) to serve as the second derivatives of aug with respect to free parameters.
info: Object of class "list".
dependencies: Object of class "integer".
expectation: Object of class "integer".
vector: Object of class "logical".
rowDiagnostics: Object of class "logical".
result: Object of class "matrix".
name: Object of class "character".

Extends

Class "MxBaseFitFunction", directly. Class "MxBaseNamed", by class "MxBaseFitFunction", distance 2. Class "MxFitFunction", by class "MxBaseFitFunction", distance 2.

Methods

No methods defined with class "MxFitFunctionGREML" in the signature.
mxFitFunctionML

References

The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.

See Also

See mxFitFunctionGREML() for creating MxFitFunctionGREML objects. See mxExpectationGREML() for creating MxExpectationGREML objects, and for more information generally concerning GREML analyses, including a complete example. More information about the OpenMx package may be found here.

Examples

showClass("MxFitFunctionGREML")

mxFitFunctionML Create MxFitFunctionML Object

Description

This function creates a new MxFitFunctionML object.

Usage

mxFitFunctionML(vector = FALSE, rowDiagnostics = FALSE, ..., fellner = as.logical(NA), verbose=0L, profileOut=c(), rowwiseParallel=as.logical(NA), jointConditionOn = c("auto", "ordinal", "continuous"))

Arguments

vector A logical value indicating whether the objective function result is the likelihood vector.
rowDiagnostics A logical value indicating whether the row-wise results of the objective function should be returned as an attribute of the fit function.
... Not used. Forces remaining arguments to be specified by name.
fellner Whether to fully expand the covariance matrix for maximum flexibility.
verbose Level of diagnostic output
profileOut Character vector naming constant coefficients to profile out of the likelihood (sometimes known as REML)
rowwiseParallel For raw data only, whether to use OpenMP to parallelize the evaluation of rows
jointConditionOn The evaluation strategy when both continuous and ordinal data are present.
Details

Fit functions are functions for which free parameter values are optimized such that the value of a cost function is minimized. The mxFitFunctionML function computes -2*(log likelihood) of the data given the current values of the free parameters and the expectation function (e.g., mxExpectationNormal or mxExpectationRAM) selected for the model.

The 'vector' argument is either TRUE or FALSE, and determines whether the objective function returns a column vector of the likelihoods, or a single -2*(log likelihood) value.

The 'rowDiagnostics' argument is either TRUE or FALSE, and determines whether the row likelihoods are returned as an attribute of the fit function. It is sometimes useful to inspect the likelihoods for outliers, diagnostics, or other anomalies.

When vector=FALSE and rowDiagnostics=TRUE, fitfunction can be referenced in the model and included in algebras as a scalar. The row likelihoods are an attribute of the fit function but are not accessible in the model during optimization. The row likelihoods are accessible to the user after the model has been run.

By default, jointConditionOn='auto' and a heuristic will be used to select the fastest algorithm. Conditioning the continuous data on ordinal will be superior when there are relatively few unique ordinal patterns. Otherwise, conditioning the ordinal data on continuous will perform better when there are relatively many ordinal patterns.

Usage Notes:

The results of the optimization can be reported using the summary function, or accessed directly in the 'output' slot of the resulting model (i.e., modelName$output). Components of the output may be referenced using the Extract functionality.

Value

Returns a new MxFitFunctionML object. One and only one MxFitFunctionML object should be included in each model along with an associated mxExpectationNormal or mxExpectationRAM object.

fitResOnly

# Look at the row likelihoods alone
fitLikeOnly <- attr(mxEval(fitfunction, tmpModelOut), 'likelihoods')
head(fitLikeOnly)
Description

The fit function used to fit a multiple group model

Usage

mxFitFunctionMultigroup(groups, ..., verbose = 0L)

Arguments

  groups        vector of fit function names (strings)
  ...           Not used. Forces subsequent arguments to be specified by name.
  verbose       the level of debugging output

Details

The mxFitFunctionMultigroup creates a fit function consisting of the sum of the fit statistics from a list of submodels provided. Thus, it aggregates fit statistics from multiple submodels.

This is conceptually similar to creating an mxAlgebra consisting of the sum of the subModel objectives and also creating an mxFitFunctionAlgebra to optimize the model based on this aggregate value.

This call to mxFitFunctionMultigroup:

mxFitFunctionMultigroup(c("model1", "model2"))

then, is almost equivalent to the following pair of statements:

mxAlgebra(model1.objective + model2.objective, name="myAlgebra")
mxFitFunctionAlgebra("myAlgebra")

The preferred method of specifying such a fit function is with this multigroup fit function, not the algebra fit function.

In addition to being more compact and readable, using mxFitFunctionMultigroup has additional side effects which are valuable for multi-group modeling.

Firstly, it aggregates analytic derivative calculations. Secondly, it allows mxRefModels to compute saturated models for raw data, as this function can learn which are the constituent submodels. Thirdly, it allows mxCheckIdentification to evaluate the local identification of the multigroup model.

Note: You can refer to the algebra generated by mxFitFunctionMultigroup when used in a group "modelName" as:

modelName.fitfunction

mxFitFunctionR

Create MxFitFunctionR Object

Description
mxFitFunctionR returns an MxFitFunctionR object.

Usage
mxFitFunctionR(fitfun, ..., units="-2lnL")

Arguments
fitfun A function that accepts two arguments.
... The initial state information to the objective function.
units (optional) The units of the fit statistic.
Details

The mxFitFunctionR function evaluates a user-defined R function called the 'fitfun'. mxFitFunctionR is useful in defining new mxFitFunctions, since any calculation that can be performed in R can be treated as an mxFitFunction.

The 'fitfun' argument must be a function that accepts two arguments. The first argument is the mxModel that should be evaluated, and the second argument is some persistent state information that can be stored between one iteration of optimization to the next iteration. It is valid for the function to simply ignore the second argument.

The function must return either a single numeric value, or a list of exactly two elements. If the function returns a list, the first argument must be a single numeric value and the second element will be the new persistent state information to be passed into this function at the next iteration. The single numeric value will be used by the optimizer to perform optimization.

The initial default value for the persitant state information is NA.

Throwing an exception (via stop) from inside fitfun may result in unpredictable behavior. You may want to wrap your code in tryCatch while experimenting.

fitfun should not call R functions that use OpenMx’s compiled backend, including (but not limited to) omxMnor(), because doing so can crash R.

Value

Returns an MxFitFunctionR object.

summary(tmpModelOut)
```

---

**mxFitFunctionRow**  
*Create an MxFitFunctionRow Object*

**Description**

`mxFitFunctionRow` returns an `MxFitFunctionRow` object.

**Usage**

```r
mxFitFunctionRow(rowAlgebra, reduceAlgebra, dimnames,  
rowResults = "rowResults", filteredDataRow = "filteredDataRow",  
existenceVector = "existenceVector", units="-2lnL")
```

**Arguments**

- `rowAlgebra`: A character string indicating the name of the algebra to be evaluated row-wise.
- `reduceAlgebra`: A character string indicating the name of the algebra that collapses the row results into a single number which is then optimized.
- `dimnames`: A character vector of names corresponding to columns be extracted from the data set.
- `rowResults`: The name of the auto-generated "rowResults" matrix. See details.
- `filteredDataRow`: The name of the auto-generated "filteredDataRow" matrix. See details.
- `existenceVector`: The name of the auto-generated "existenceVector" matrix. See details.
- `units`: (optional) The units of the fit statistic.
**Details**

Fit functions are functions for which free parameter values are optimized such that the value of a cost function is minimized. The `mxFitFunctionRow` function evaluates a user-defined `MxAlgebra` object called the `rowAlgebra` in a row-wise fashion. It then stores results of the row-wise evaluation in another `MxAlgebra` object called the `rowResults`. Finally, the `mxFitFunctionRow` function collapses the row results into a single number which is then used for optimization. The `MxAlgebra` object named by the `reduceAlgebra` collapses the row results into a single number.

The `filteredDataRow` is populated in a row-by-row fashion with all the non-missing data from the current row. You cannot assume that the length of the `filteredDataRow` matrix remains constant (unless you have no missing data). The `existenceVector` is populated in a row-by-row fashion with a value of 1.0 in column j if a non-missing value is present in the data set in column j, and a value of 0.0 otherwise. Use the functions `omxSelectRows`, `omxSelectCols`, and `omxSelectRowsAndCols` to shrink other matrices so that their dimensions will be conformable to the size of `filteredDataRow`.

**Value**

Returns a new `MxFitFunctionRow` object. Only one `MxFitFunction` object should be included in each model. There is no need for an `MxExpectation` object when using `mxFitFunctionRow`.

**Examples**

```R
# Model that adds two data columns row-wise, then sums that column # Notice no optimization is performed here.
library(OpenMx)

xdat <- data.frame(a=rnorm(10), b=1:10) # Make data set
amod <- mxModel(model="example1",
    mxData(observed=xdat, type="raw"),
    mxAlgebra(sum(filteredDataRow), name = "rowAlgebra"),
    mxAlgebra(sum(rowResults), name = "reduceAlgebra"),
    mxFitFunctionRow(
        rowAlgebra='rowAlgebra',
        reduceAlgebra='reduceAlgebra',
        dimnames=c('a','b'))
)
amodOut <- mxRun(amod)
mxEval(rowResults, model=amodOut)
mxEval(reduceAlgebra, model=amodOut)
```
# Model that finds the parameter that minimizes the sum of the
# squared difference between the parameter and a data row.

bmod <- mxModel(model="example2",
    mxData(observed=xdat, type="raw"),
    mxMatrix(values=.75, ncol=1, nrow=1, free=TRUE, name="B"),
    mxAlgebra((filteredDataRow - B) ^ 2, name="rowAlgebra"),
    mxAlgebra(sum(rowResults), name="reduceAlgebra"),
    mxFitFunctionRow(
        rowAlgebra="rowAlgebra",
        reduceAlgebra='reduceAlgebra',
        dimnames=c('a'))
)
bmodOut <- mxRun(bmod)
mxEval(B, model=bmodOut)
mxEval(reduceAlgebra, model=bmodOut)
mxEval(rowResults, model=bmodOut)

mxFitFunctionWLS Create MxFitFunctionWLS Object

Description

This function creates a new MxFitFunctionWLS object.

Usage

mxFitFunctionWLS(weights = "ULS")

Arguments

weights Ignored. Uses weights from mxData

Details

Fit functions are functions for which free parameter values are optimized such that the value of a cost function is minimized. The mxFitFunctionWLS function computes the weighted least squares difference between the data and the model-implied expectations for the data based on the free parameters and the expectation function (e.g., mxExpectationNormal or mxExpectationRAM) selected for the model.

The 'weights' argument is ignored. Rather the weights are provided in the mxData object, often generated by the mxDataWLS function.

Usage Notes:

The results of the optimization can be reported using the summary function, or accessed directly in the 'output' slot of the resulting model (i.e., modelName$output). Components of the output may be referenced using the Extract functionality.
Value

Returns a new MxFitFunctionWLS object. One and only one MxFitFunctionWLS object should be included in each model along with an associated mxExpectationNormal or mxExpectationRAM object.

References

The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.

wdata)

# Fit the model and print a summary
tmpModelOut <- mxRun(tmpModel)
summary(tmpModelOut)
```

---

**MxFlatModel-class**  
*MxFlatModel*

**Description**

This is an internal class and should not be used.

---

**mxGenerateData**  
*Generate data based on an MxModel object*

**Description**

This function returns a new (simulated) data set based on the model-implied distribution provided.

**Usage**

```r
mxGenerateData(model, nrows, returnModel=FALSE, use.miss = TRUE, ..., .backend=TRUE)
```

**Arguments**

- `model`  
  A data.frame or MxModel object upon which the data are generated.

- `nrows`  
  Numeric. The number of rows of data to generate.

- `returnModel`  
  Logical. Return data.frames if FALSE or model populated with new data if TRUE.

- `use.miss`  
  Logical. Whether to approximate the missingness pattern of the original data.

- `...`  
  Not used; forces remaining arguments to be specified by name.

- `.backend`  
  Whether to use the backend to generate data
Details

When given a data.frame as a model, the model is assumed to be saturated multivariate Gaussian and the expected distribution is obtained using `mxDataWLS`. In this case, the default number of rows is assumed to be the number of rows in the original data.frame, but any other number of rows can also be requested.

When given an MxModel, the model-implied means and covariance are extracted. It then generates data with the same mean and covariance. Data can be generated based on Normal (mxExpectationNormal), RAM (mxExpectationRAM), LISREL (mxExpectationLISREL), and state space (mxExpectationStateSpace) models.

Please note that this function samples data from the model-implied distribution(s); it does not sample from the data object in the model. That is, this function generates new data rather than pulling data that already exist from the model.

Thresholds and ordinal data are implemented by generating continuous data and then using `cut` and `mxFactor` to break the continuous data at the thresholds into an ordered factor.

If the model has definition variables, then a data set must be included in the model object and the number of rows requested must match the number of rows in the model data. In this case the means, covariance, and thresholds are reevaluated for each row of data, potentially creating a a different mean, covariance, and threshold structure for every generated row of data.

For state space models (i.e. models with an mxExpectationStateSpace or mxExpectationStateSpaceContinuousTime expectation), the data are generated based on the autoregressive structure of the model. The rows of data in a state space model are not independent replicates of a stationary process. Rather, they are the result of a latent (possibly non-stationary) autoregressive process. For state space models different rows of data often correspond to different times. As alluded to above, data generation works for discrete time state space models and hybrid continuous-discrete time state space models. The latter have a continuous process that is measured as discrete times.

Value

A data.frame, list of data.frames, or model populated with the new data (depending on the `returnModel` parameter). Raw data is always returned even if the original model contained covariance or some other non-raw data.

Examples

```r
#--------
# Create data based on state space model.
require(OpenMx)
nvar <- 5
varnames <- paste("x", 1:nvar, sep="")
ssModel <- mxModel(model="State Space Manual Example",
  mxMatrix("Full", 1, 1, TRUE, .3, name="A"),
  mxMatrix("Zero", 1, 1, name="B"),
  mxMatrix("Full", nvar, 1, TRUE, .6, name="C", dimnames=list(varnames, "F1"),
```
mxMatrix("Zero", nvar, 1, name="D"),
mxMatrix("Diag", 1, 1, FALSE, 1, name="Q"),
mxMatrix("Diag", nvar, nvar, TRUE, .2, name="R"),
mxMatrix("Zero", 1, 1, name="x0"),
mxMatrix("Diag", 1, 1, FALSE, 1, name="P0"),
mxMatrix("Zero", 1, 1, name="u"),
mxExpectationStateSpace("A", "B", "C", "D", "Q", "R", "x0", "P0", "u"),
mxFitFunctionML()
)

ssData <- mxGenerateData(ssModel, 200) # 200 time points

# Add simulated data to model
ssModel <- mxModel(ssModel, mxData(ssData, 'raw'))

# Fit model to simulated data
ssRun <- mxRun(ssModel)

# Compare parameters estimated from random data to
# their true generating values
cbind(Rand = omxGetParameters(ssRun), Gen = omxGetParameters(ssModel))
# Note the parameters should be "close" (up to sampling error)
# to the generating values

require(OpenMx)
manifests <- paste("x", 1:5, sep="")
latents <- c("G")
factorModel <- mxModel("One Factor",
type="RAM",
manifestVars = manifests,
latentVars = latents,
mxPath(from=latents, to=manifests, values=.8),
mxPath(from=manifests, arrows=2, values=.2),
mxPath(from=latents, arrows=2,
free=FALSE, values=1.0),
mxPath(from = 'one', to = manifests))
factorData <- mxGenerateData(factorModel, 100)

factorModel <- mxModel(factorModel,
mxData(observed= cov(factorData), type="cov",
numObs=nrow(factorData),
means = colMeans(factorData))
factorRun <- mxRun(factorModel)

cbind(Rand=omxGetParameters(factorRun), Gen=omxGetParameters(factorModel))
**Description**

This function extracts the expected means, covariance, or thresholds from a model.

**Usage**

```r
mxGetExpected(model, component, defvar.row=1, subname=model$name)
imxGetExpectationComponent(model, component, defvar.row=1, subname=model$name)
```

**Arguments**

- `model`: MxModel object from which to extract the expectation component.
- `component`: A character. The name of the component to extract.
- `defvar.row`: A row index. Which row to load for definition variables.
- `subname`: Name of the submodel to evaluate.

**Details**

The expected means, covariance, or thresholds can be extracted from Normal (mxExpectationNormal), RAM (mxExpectationRAM), and LISREL (mxExpectationLISREL) models. When more than one component is requested, the components will be returned as a list.

If component 'vector' is requested then the non-redundent coefficients of the expected manifest distribution will be returned as a vector.

If component 'standVector' is requested then the same parameter structure as 'vector' is returned, but it is standardized. For Normal expectations the covariances are returned as correlations, the means are returned as zeros, and the thresholds are returned as z-scores. For the thresholds the z-scores are computed by using the model-implied means and variances.

Note that capitalization is ignored for the 'standVector' option, so 'standvector' is also acceptable.

**Value**

See details.

**References**

**Examples**

```r
#----------
require(OpenMx)
manifests <- paste("x", 1:5, sep="")
latents <- c("G")
factorModel <- mxModel("One Factor",
type="RAM",
manifestVars = manifests,
latentVars = latents,
mxPath(from=latents, to=manifests),
mxPath(from=manifests, to=latents),
mxPath(from=latents, to=latents),
mxPath(from=manifests, to=manifests),
mxPath(from=latents, to=manifests)
)```
mxPath(from=manifests, arrows=2),
mxPath(from=latents, arrows=2,
  free=FALSE, values=1.0),
mxPath(from = 'one', to = manifests))

mxGetExpected(factorModel, "covariance")
# oops. Starting values indicate a zero covariance matrix.
# Probably should adjust them.

---

**mxGREMLDataHandler**  
*Helper Function for Structuring GREML Data*

**Description**
This function takes a dataframe or matrix and uses it to setup the 'y' and 'X' matrices for a GREML analysis; this includes trimming out NAs from 'X' and 'y.' The result is a matrix the first column of which is the 'y' vector, and the remaining columns of which constitute 'X.'

**Usage**

```
mxGREMLDataHandler(data, yvars=character(0), Xvars=list(), addOnes=TRUE,
  blockByPheno=TRUE, staggerZeroes=TRUE)
```

**Arguments**

- **data**  
  Either a dataframe or matrix, with column names, containing the variables to be used as phenotypes and covariates in 'y' and 'X,' respectively.

- **yvars**  
  Character vector. Each string names a column of the raw dataset, to be used as a phenotype.

- **Xvars**  
  A list of data column names, specifying the covariates to be used with each phenotype. The list should have the same length as argument yvars.

- **addOnes**  
  Logical; should lead columns of ones (for the regression intercepts) be adhered to the covariates when assembling the 'X' matrix? Defaults to TRUE.

- **blockByPheno**  
  Logical; relevant to polyphenotype analyses. If TRUE (default), then the resulting 'y' will contain phenotype #1 for individuals 1 thru n, phenotype #2 for individuals 1 thru n, ... If FALSE, then observations are "blocked by individual", and the resulting 'y' will contain individual #1's scores on phenotypes 1 thru p, individual #2's scores on phenotypes 1 thru p, ... Note that in either case, 'X' will be structured appropriately for 'y.'

- **staggerZeroes**  
  Logical; relevant to polyphenotype analyses. If TRUE (default), then each phenotype's covariates in 'X' are "staggered," and 'X' is padded out with zeroes. If FALSE, then 'X' is formed simply by stacking the phenotypes' covariates; this requires each phenotype to have the same number of covariates (i.e., each character vector in Xvars must be of the same length). The default (TRUE) is intended for instances where the multiple phenotypes truly are different variables,
whereas staggerZeroes=FALSE is intended for instances where the multiple "phenotypes" actually represent multiple observations on the same variable. One example of the latter case is longitudinal data where the multiple "phenotypes" are repeated measures on a single phenotype.

Details

For a monophenotype analysis (only), argument Xdata can be a character vector. In a polyphenotype analysis, if the same covariates are to be used with all phenotypes, then Xdata can be a list of length 1.

Note the synergy between the output of mxGREMLDataHandler() and arguments dataset.is.yX and casesToDropFromV to mxExpectationGREML().

If the dataframe or matrix supplied for argument data has n rows, and argument yvars is of length p, then the resulting 'y' and 'X' matrices will have np rows. Then, if either matrix contains any NA's, the rows containing the NA's are trimmed from both 'X' and 'y' before being returned in the output (in which case they will obviously have fewer than np rows). Function mxGREMLDataHandler() reports which rows of the full-size 'X' and 'y' were trimmed out due to missing observations. These row indices can be provided as argument casesToDropFromV to mxExpectationGREML().

Value

A list with these two components:

yX Numeric matrix. The first column is the phenotype vector, 'y,' while the remaining columns constitutethe 'X' matrix of covariates. If this matrix is used as the raw dataset for a model, then the model's GREML expectation can be constructed with dataset.is.yX=TRUE in mxExpectationGREML().

casesToDrop Numeric vector. Contains the indices of the rows of the 'y' and 'X' that were dropped due to containing NA's. Can be provided as as argument casesToDropFromV to mxExpectationGREML().

Examples

dat <- cbind(rnorm(100),rep(1,100))
colnames(dat) <- c("y","x")
dat[42,1] <- NA
dat[57,2] <- NA
dat2 <- mxGREMLDataHandler(data=dat, yvars="y", Xvars=list("x"),
  addOnes = FALSE)
str(dat2)
mxKalmanScores

**MxInterval-class**

**MxInterval**

**Description**

This is an internal class and should not be used directly.

**See Also**

mxCI

**mxKalmanScores**

**Estimate Kalman scores and error covariance matrices**

**Description**

This function creates the Kalman predicted, Kalman updated, and Rauch-Tung-Striebel smoothed latent state and error covariance estimates for an MxModel object that has an MxExpectationStateSpace object.

**Usage**

mxKalmanScores(model, data=NA, frontend=TRUE)

**Arguments**

- **model**: An MxModel object with an MxExpectationStateSpace.
- **data**: An optional data.frame or matrix.
- **frontend**: When TRUE, compute score in the frontend, otherwise use the backend.

**Details**

This is a helper function that computes the results of the classical Kalman filter. In particular, for every row of data there is a predicted latent score, an error covariance matrix for the predicted latent scores that provides an estimate of the predictions precision, an updated latent score, and an updated error covariance matrix for the updated lated scores. Additionally, the Rauch-Tung-Striebel (RTS) smoothed latent scores and error covariance matrices are returned.
Value

A list with components xPredicted, PPredicted, xUpdated, PUpdated, xSmoothed, PSmoothed, m2ll, and L. When using backend scores, this list also has components for yPredicted and SPredicted which have the same number of time points as the other components but relate to the observed variables instead of the latent variables. The rows of xPredicted, xUpdated, and xSmoothed correspond to different time points. The columns are the different latent variables. The third index of PPredicted, PUpdated, and PSmoothed corresponds to different times. This works nicely with the R default print method for arrays. At each time there is a covariance matrix of the latent variable scores. For all items listed below, the first element goes with the zeroth time point (See example).

- **xPredicted**: matrix of Kalman predicted scores
- **PPredicted**: array of Kalman predicted error covariances
- **xUpdated**: matrix of Kalman updated scores
- **PUpdated**: array of Kalman updated error covariances
- **xSmoothed**: matrix of RTS smoothed scores
- **PSmoothed**: array of RTS smoothed error covariances
- **m2ll**: minus 2 log likelihood
- **L**: likelihood, i.e., the multivariate normal probability density
- **yPredicted**: matrix of Kalman predicted scores for the observed variables, i.e., the predicted means. Only available for backend scores.
- **SPredicted**: array of Kalman predicted error covariances for the observed variables, i.e., the predicted covariances. Only available for backend scores.

MxLISRELModel-class

**MxLISRELModel**

**Description**

This is an internal class and should not be used directly.
mxLISRELObjective

Create MxLISRELObjective Object

Description

This function creates a new MxLISRELObjective object.

Usage

mxLISRELObjective(LX=NA, LY=NA, BE=NA, GA=NA, PH=NA, PS=NA, TD=NA, TE=NA, TH=NA, TX = NA, TY = NA, KA = NA, AL = NA, 
dimnames = NA, thresholds = NA, vector = FALSE, threshnames = dimnames)

Arguments

LX  An optional character string indicating the name of the 'LX' matrix.
LY  An optional character string indicating the name of the 'LY' matrix.
BE  An optional character string indicating the name of the 'BE' matrix.
GA  An optional character string indicating the name of the 'GA' matrix.
PH  An optional character string indicating the name of the 'PH' matrix.
PS  An optional character string indicating the name of the 'PS' matrix.
TD  An optional character string indicating the name of the 'TD' matrix.
TE  An optional character string indicating the name of the 'TE' matrix.
TH  An optional character string indicating the name of the 'TH' matrix.
TX  An optional character string indicating the name of the 'TX' matrix.
TY  An optional character string indicating the name of the 'TY' matrix.
KA  An optional character string indicating the name of the 'KA' matrix.
AL  An optional character string indicating the name of the 'AL' matrix.
dimnames   An optional character vector that is currently ignored
thresholds An optional character string indicating the name of the thresholds matrix.
vector    A logical value indicating whether the objective function result is the likelihood vector.
threshnames An optional character vector to be assigned to the column names of the thresholds matrix.

Details

Objective functions are functions for which free parameter values are chosen such that the value of the objective function is minimized. The mxLISRELObjective provides maximum likelihood estimates of free parameters in a model of the covariance of a given MxData object. This model is defined by Linear Structural RELations (LISREL; Jöreskog & Sörbom, 1982, 1996). Arguments
'LX' through 'AL' must refer to MxMatrix objects with the associated properties of their respective matrices in the LISREL modeling approach.

The full LISREL specification has 13 matrices and is sometimes called the extended LISREL model. It is defined by the following equations.

\[ \eta = \alpha + B \eta + \Gamma \xi + \zeta \]
\[ y = \tau_y + \Lambda_y \eta + \epsilon \]
\[ x = \tau_x + \Lambda_x \xi + \delta \]

The table below is provided as a quick reference to the numerous matrices in LISREL models. Note that NX is the number of manifest exogenous (independent) variables, the number of Xs. NY is the number of manifest endogenous (dependent) variables, the number of Ys. NK is the number of latent exogenous variables, the number of Ksis or Xis. NE is the number of latent endogenous variables, the number of etas.

</tbody>
</table>

From the extended LISREL model, several submodels can be defined. Subtypes of the LISREL model are defined by setting some of the arguments of the LISREL objective to NA. Note that because the default values of each LISREL matrix is NA, setting a matrix to NA can be accomplished by simply not giving it any other value.

The first submodel is the LISREL model without means.

\[ \eta = B \eta + \Gamma \xi + \zeta \]
\[ y = \Lambda_y \eta + \epsilon \]
\[ x = \Lambda_x \xi + \delta \]

The LISREL model without means requires 9 matrices: LX, LY, BE, GA, PH, PS, TD, TE, and TH. Hence this LISREL model has TX, TY, KA, and AL as NA. This can be accomplished by leaving these matrices at their default values.
The TX, TY, KA, and AL matrices must be specified if either the mxData type is “cov” or “cor” and a means vector is provided, or if the mxData type is “raw”. Otherwise the TX, TY, KA, and AL matrices are ignored and the model without means is estimated.

A second submodel involves only endogenous variables.

\[
\eta = B\eta + \zeta \\
y = \Lambda_y\eta + \epsilon
\]

The endogenous-only LISREL model requires 4 matrices: LY, BE, PS, and TE. The LX, GA, PH, TD, and TH must be NA in this case. However, means can also be specified, allowing TY and AL if the data are raw or if observed means are provided.

Another submodel involves only exogenous variables.

\[
x = \Lambda_x\xi + \delta
\]

The exogenous-model model requires 3 matrices: LX, PH, and TD. The LY, BE, GA, PS, TE, and TH matrices must be NA. However, means can also be specified, allowing TX and KA if the data are raw or if observed means are provided.

The model that is run depends on the matrices that are not NA. If all 9 matrices are not NA, then the full model is run. If only the 4 endogenous matrices are not NA, then the endogenous-only model is run. If only the 3 exogenous matrices are not NA, then the exogenous-only model is run. If some endogenous and exogenous matrices are not NA, but not all of them, then appropriate errors are thrown. Means are included in the model whenever their matrices are provided.

The MxMatrix objects included as arguments may be of any type, but should have the properties described above. The mxLISRELObjective will not return an error for incorrect specification, but incorrect specification will likely lead to estimation problems or errors in the mxRun function.

Like the mxRAMObjective, the mxLISRELObjective evaluates with respect to an MxData object. The MxData object need not be referenced in the mxLISRELObjective function, but must be included in the MxModel object. mxLISRELObjective requires that the ‘type’ argument in the associated MxData object be equal to ‘cov’, ‘cor’, or ‘raw’.

To evaluate, place MxLISRELObjective objects, the mxData object for which the expected covariance approximates, referenced MxAlgebra and MxMatrix objects, and optional MxBounds and MxConstraint objects in an MxModel object. This model may then be evaluated using the mxRun function. The results of the optimization can be found in the ‘output’ slot of the resulting model, and may be obtained using the mxEval function.

Value

Returns a new MxLISRELObjective object. MxLISRELObjective objects should be included with models with referenced MxAlgebra, MxData and MxMatrix objects.

**MxListOrNull-class**

An optional list

---

**Description**

An optional list

---

**mxMakeNames**

**mxMakeNames**

---

**Description**

Adjust a character vector so that it can be used as MxMatrix column or row names. OpenMx is (much) more restrictive than base R’s make.names.

**Usage**

`mxMakeNames(names, unique = FALSE)`

**Arguments**

- names: a character vector
- unique: whether the pass the result through `make.unique`

**See Also**

`make.names`
mxMatrix

Examples

demo <- c("", "103", "data", "foo.bar[3,2]", "+!", "+")
mxMakeNames(demo, unique=TRUE)

mxMatrix

Create MxMatrix Object

Description

This function creates a new MxMatrix object.

Usage

mxMatrix(type = "Full", nrow = NA, ncol = NA,
          free = FALSE, values = NA, labels = NA, lbound = NA,
          ubound = NA, byrow = getOption("mxByrow"),
          dimnames = NA, name = NA,
          condenseSlots=getOption("mxCondenseMatrixSlots"),
          ..., joinKey=as.character(NA), joinModel=as.character(NA))

Arguments

type A character string indicating the matrix type, where type indicates the range
       of values and equalities in the matrix. Must be one of: ‘Diag’, ‘Full’, ‘Iden’,

nrow Integer; the desired number of rows. One or both of ‘nrow’ and ‘ncol’ is re-
       quired when ‘values’, ‘free’, ‘labels’, ‘lbound’, and ‘ubound’ arguments are not
       matrices, depending on the desired MxMatrix type.

ncol Integer; the desired number of columns. One or both of ‘nrow’ and ‘ncol’ is
       required when ‘values’, ‘free’, ‘labels’, ‘lbound’, and ‘ubound’ arguments are
       not matrices, depending on the desired MxMatrix type.

free A vector or matrix oflogicals for free parameter specification. A single ‘TRUE’
       or ‘FALSE’ will set all allowable variables to free or fixed, respectively.

values A vector or matrix of numeric starting values. By default, all values are set to
       zero.

labels A vector or matrix of characters for variable label specification.

lbound A vector or matrix of numeric lower bounds. Default bounds are specified with
       an NA.

ubound A vector or matrix of numeric upper bounds. Default bounds are specified with
       an NA.

byrow Logical; defaults to value of global option ’mxByRow’. If FALSE (default),
       the ‘values’, ‘free’, ‘labels’, ‘lbound’, and ‘ubound’ matrices are populated by
       column rather than by row.
The `mxMatrix` function creates `MxMatrix` objects, which consist of five matrices and a 'type' argument. The 'values' matrix is made up of numeric elements whose usage and capabilities in other functions are defined by the 'free' matrix. If an element is specified as a fixed parameter in the 'free' matrix, then the element in the 'values' matrix is treated as a constant value and cannot be altered or updated by an objective function when included in an `mxRun` function. If an element is specified as a free parameter in the 'free' matrix, the element in the 'value' matrix is considered a starting value and can be changed by an objective function when included in an `mxRun` function.

Element labels beginning with 'data.' can be used if the `MxMatrix` is to be used in an `MxModel` object that has a raw dataset (i.e., an `MxData` object of type="raw"). Such a label instructs OpenMx to use a particular column of the raw dataset to fill in the value of that element. For historical reasons, the variable contained in that column is called a "definition variable." For example, if an `MxMatrix` element has the label 'data.x', then OpenMx will use the first value of the data column named "x" when evaluating the fitfunction for the first row, and will use the second value of column "x" when evaluating the fitfunction for the second row, and so on. After the call to `mxRun()`, the values for elements labeled with 'data.x' are returned as the value from the first (i.e., first before any automated sorting is done) element of column "x" in the data.

Objects created by the `mxMatrix()` function are of a specific 'type', which specifies the number and location of parameters in the 'labels' matrix and the starting values in the 'values' matrix. Input 'values', 'free', and 'labels' matrices must be of appropriate shape and have appropriate values for the matrix type requested. Nine types of matrices are supported:

- 'Diag' matrices must be square, and only elements on the principal diagonal may be specified as free parameters or take nonzero values.
- 'Full' matrices may be either rectangular or square, and all elements in the matrix may be freely estimated. This type is the default for the `mxMatrix()` function.
- 'Iden' matrices must be square, and consist of no free parameters. Matrices of this type have a value of 1 for all entries on the principle diagonal, and 0 in all off-diagonal entries.
- 'Lower' matrices must be square, with a value of 0 for all entries in the upper triangle and no free parameters in the upper triangle.
- 'Sdiag' matrices must be square, with a value of 0 for all entries in the upper triangle and along the diagonal. No free parameters in the upper triangle or along the diagonal.
- 'Symm' matrices must be square, and elements in the principle diagonal and lower triangular portion of the matrix may be free parameters.
- 'Stand' matrices are symmetric matrices (see 'Symm') with 1's along the main diagonal.
- 'Unit' matrices may be either rectangular or square, and contain no free parameters. All elements in matrices of this type have a value of 1.
- 'Zero' matrices may be either rectangular or square, and contain no free parameters. All elements in matrices of this type have a value of 0.
When ‘type’ is ‘Lower’ or ‘Symm’, then the arguments to ‘free’, ‘values’, ‘labels’, ‘lboud’, or ‘ubound’ may be vectors of length \( N \times (N + 1)/2 \), where \( N \) is the number of rows and columns of the matrix. When ‘type’ is ‘Sdiag’ or ‘Stand’, then the arguments to ‘free’, ‘values’, ‘labels’, ‘lboud’, or ‘ubound’ may be vectors of length \( N \times (N - 1)/2 \).

Value

Returns a new MxMatrix object, which consists of a ‘values’ matrix of numeric starting values, a ‘free’ matrix describing free parameter specification, a ‘labels’ matrix of labels for the variable names, and ‘lboud’ and ‘ubound’ matrices of the lower and upper parameter bounds. This MxMatrix object can be used as an argument in the mxAlgebra(), mxBounds(), mxConstraint() and mxModel() functions.

**MxMatrix-class**  

**MxMatrix Class**

**Description**

MxMatrix is a virtual S4 class that comprises the nine types of matrix objects used by OpenMx (see `mxMatrix()` for details). An MxMatrix object is a named entity. New instances of this class can be created using the function `mxMatrix()`. MxMatrix objects may be used as arguments in other functions from the OpenMx package, including `mxAlgebra()`, `mxConstraint()`, and `mxModel()`.

**Objects from the Class**

All nine types of object that the class comprises can be created via `mxMatrix()`.

**Slots**

- **name**: Character string; the name of the MxMatrix object. Note that this is the object's "Mx name" (so to speak), which identifies it in OpenMx's internal namespace, rather than the symbol identifying it in R's workspace. Use of MxMatrix objects in an `mxAlgebra` or `mxConstraint` function requires reference by name.

- **values**: Numeric matrix of values. If an element is specified as a fixed parameter in the 'free' matrix, then the element in the 'values' matrix is treated as a constant value and cannot be altered or updated by an objective function when included in an `mxRun()` function. If an
element is specified as a free parameter in the 'free' matrix, the element in the 'value' matrix is considered a starting value and can be changed by an objective function when included in an \texttt{mxRun()} function.

\textbf{labels}: Matrix of character strings which provides the labels of free and fixed parameters. Fixed parameters with identical labels must have identical values. Free parameters with identical labels impose an equality constraint. The same label cannot be applied to a free parameter and a fixed parameter. A free parameter with the label 'NA' implies a unique free parameter, that cannot be constrained to equal any other free parameter.

\textbf{free}: Logical matrix specifying whether each element is free versus fixed. An element is a free parameter if-and-only-if the corresponding value in the 'free' matrix is 'TRUE'. Free parameters are elements of an \texttt{MxMatrix} object whose values may be changed by a fitfunction when that \texttt{MxMatrix} object is included in an \texttt{MxModel} object and evaluated using the \texttt{mxRun()} function.

\textbf{lbound}: Numeric matrix of lower bounds on free parameters.

\textbf{ubound}: Numeric matrix of upper bounds on free parameters.

\textbf{.squareBrackets}: Logical matrix: used internally by OpenMx. Identifies which elements have labels with square brackets in them.

\textbf{.persist}: Logical; used internally by OpenMx. Governs how \texttt{mxRun()} handles the \texttt{MxMatrix} object when it is inside the \texttt{MxModel} being run.

\textbf{.condenseSlots}: Logical; used internally by OpenMx. If FALSE, then the matrices in the 'values', 'labels', 'free', 'lbound', and 'ubound' slots are all of equal dimensions. If TRUE, then the last four of those slots will "condense" a matrix consisting entirely of FALSE or NA down to 1x1.

\textbf{display}: Character string; used internally by OpenMx when parsing \texttt{MxAlgebras}.

\textbf{dependencies}: Integer; used internally by OpenMx when parsing \texttt{MxAlgebras}.

\textbf{Methods}

\begin{verbatim}
  \$ signature(x = "MxMatrix"): ...
  \$<- signature(x = "MxMatrix"): ...
  [ signature(x = "MxMatrix"): ...
  [<- signature(x = "MxMatrix"): ...
  \textbf{dim} signature(x = "MxMatrix"): ...
  \textbf{dimnames} signature(x = "MxMatrix"): ...
  \textbf{dimnames<-} signature(x = "MxMatrix"): ...
  \textbf{length} signature(x = "MxMatrix"): ...
  \textbf{names} signature(x = "MxMatrix"): ...
  \textbf{ncol} signature(x = "MxMatrix"): ...
  \textbf{nrow} signature(x = "MxMatrix"): ...
  \textbf{print} signature(x = "MxMatrix"): ...
  \textbf{show} signature(object = "MxMatrix"): ...
\end{verbatim}

Note that some methods are documented separately (see below, under "See Also").
mxMI

Estimate Modification Indices for MxModel Objects

Description

This function estimates the change in fit function value resulting from freeing currently fixed parameters.

Usage

mxMI(model, matrices=NA, full=TRUE)

Arguments

model

An MxModel for which modification indices are desired.

matrices

Character vector. The names of the matrices in which to search for modification

full

Logical. Whether or not to return the full modification index in addition to the restricted.

Details

Modification indices provide an estimate of how much the fit function value would change if a parameter that is currently fixed was instead freely estimated. There are two versions of this estimate: a restricted version and an full version. The restricted version is reported as the MI and is much faster to compute. The full version is reported as MI.Full. The full version accounts for the total change in fit function value resulting from the newly freed parameter. The restricted version only accounts for the change in the fit function due to the movement of the new free parameter. In particular, the restricted version does not account for the change in fit function value due to the other free parameters moving in response to the new parameter.

The algorithm respects fixed parameter labels. That is, when a fixed parameter has a label and occurs in more than one spot, then that fixed parameter is freed in all locations in which it occurs to evaluate the modification index for that fixed parameter.
When the fit function is in minus two log likelihood units (e.g. \texttt{mxFitFunctionML}), then the MI will be approximately chi squared distributed with 1 degree of freedom. Using a p-value of 0.01 has been suggested. Hence, a MI greater than $q_{\text{chisq}}(p=1-0.01, \ df=1)$, or 6.63, is suggestive of a modification.

Users should be cautious in their use of modification indices. If a model was created with the aid of MIs, then it should always be reported. \textit{Do not pretend that you have a theoretical reason for part of a model that was put there because it was suggested by a modification index. This is fraud.} When using modification indices there are two options for best practices. First, you can report the analyses as exploratory. Document all the explorations that you did, and know that your results may or may not generalize. Second, you can use cross-validation. Reserve part of your data for exploration, and use the remaining data to test if the exploratory model generalizes to new data.

\textbf{Value}

A named list with components

- \textbf{MI} The restricted modification index.
- \textbf{MI.Full} The full modification index.
- \textbf{plusOneParamModels} A list of models with one additional free parameter

\textbf{References}

The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.

\textbf{Examples}

```r
# Create a model
require(OpenMx)
data(demoOneFactor)
manifests <- names(demoOneFactor)
latents <- c("G")
factorModel <- mxModel("One Factor",
type="RAM",
manifestVars = manifests,
latentVars = latents,
mxPath(from=latents, to=manifests),
mxPath(from=manifests, arrows=2),
mxPath(from=latents, arrows=2,
free=FALSE, values=1.0),
mxPath(from = 'one', to = manifests),
mxData( observed = 'cov(demoOneFactor)', type="cov", numObs=500,
means = colMeans(demoOneFactor)))

# No SEs for speed
factorModel <- mxOption(factorModel, 'Standard Errors', 'No')
factorRun <- mxRun(factorModel)

# See if it should be modified
# Notes
# Using full=FALSE for faster performance
```
mxMLObjective

Description

WARNING: Objective functions have been deprecated as of OpenMx 2.0.

Please use mxExpectationNormal() and mxFitFunctionML() instead. As a temporary workaround, mxMLObjective returns a list containing an MxExpectationNormal object and an MxFitFunctionML object.

mxMLObjective(covariance, means = NA, dimnames = NA, thresholds = NA) All occurrences of mxMLObjective(covariance, means = NA, dimnames = NA, thresholds = NA)
Should be changed to

mxExpectationNormal(covariance, means = NA, dimnames = NA, thresholds = NA, threshnames = dimnames) mxFitFunctionML(vector = FALSE)

Arguments

covariance A character string indicating the name of the expected covariance algebra.
means An optional character string indicating the name of the expected means algebra.
dimnames An optional character vector to be assigned to the dimnames of the covariance and means algebras.
thresholds An optional character string indicating the name of the thresholds matrix.

Details

NOTE: THIS DESCRIPTION IS DEPRECATED. Please change to using mxExpectationNormal and mxFitFunctionML as shown in the example below.

Objective functions are functions for which free parameter values are chosen such that the value of the objective function is minimized. The mxMLObjective function uses full-information maximum likelihood to provide maximum likelihood estimates of free parameters in the algebra defined by the 'covariance' argument given the covariance of an MxData object. The 'covariance' argument takes an MxAlgebra object, which defines the expected covariance of an associated MxData object. The 'dimnames' arguments takes an optional character vector. If this argument is not a single NA, then this vector be assigned to be the dimnames of the means vector, and the row and columns dimnames of the covariance matrix.

def mxMLObjective(
  covariance = NULL,
  means = NA,
  dimnames = NA,
  thresholds = NA
)
mxMLObjective evaluates with respect to an MxData object. The MxData object need not be referenced in the mxMLObjective function, but must be included in the MxModel object. mxMLObjective requires that the 'type' argument in the associated MxData object be equal to 'cov' or 'cov'. The 'covariance' argument of this function evaluates with respect to the 'matrix' argument of the associated MxData object, while the 'means' argument of this function evaluates with respect to the 'vector' argument of the associated MxData object. The 'means' and 'vector' arguments are optional in both functions. If the 'means' argument is not specified (NA), the optional 'vector' argument of the MxData object is ignored. If the 'means' argument is specified, the associated MxData object should specify a 'means' argument of equivalent dimension as the 'means' algebra.

dimnames must be supplied where the matrices referenced by the covariance and means algebras are not themselves labeled. Failure to do so leads to an error noting that the covariance or means matrix associated with the ML objective does not contain dimnames.

To evaluate, place MxMLObjective objects, the mxData object for which the expected covariance approximates, referenced MxAlgebra and MxMatrix objects, and optional MxBounds and MxConstraint objects in an MxModel object. This model may then be evaluated using the mxRun function. The results of the optimization can be found in the 'output' slot of the resulting model, or using the mxEval function.

Value

Returns a list containing an MxExpectationNormal object and an MxFitFunctionML object.

Examples

# Create and fit a model using mxMatrix, mxAlgebra, mxExpectationNormal, and mxFitFunctionML
library(OpenMx)

# Simulate some data
x=rnorm(1000, mean=0, sd=1)
y= 0.5*x + rnorm(1000, mean=0, sd=1)
tmpFrame <- data.frame(x, y)
tmpNames <- names(tmpFrame)

# Define the matrices
S <- mxMatrix(type = "Full", nrow = 2, ncol = 2, values=c(1,0,0,1),
      free=c(TRUE,FALSE,FALSE,TRUE), labels=c("Vx", NA, NA, "Vy"), name = "S")
A <- mxMatrix(type = "Full", nrow = 2, ncol = 2, values=c(0,1,0,0),
      free=c(FALSE,TRUE,FALSE,FALSE), labels=c(NA, "b", NA, NA), name = "A")
I <- mxMatrix(type="Iden", nrow=2, ncol=2, name="I")

# Define the expectation
expCov <- mxAlgebra(solve(I-A) %*% S %*% t(solve(I-A)), name="expCov")
expFunction <- mxExpectationNormal(covariance="expCov", dimnames=tmpNames)

# Choose a fit function
fitFunction <- mxFitFunctionML()

# Define the model
tmpModel <- mxModel(model="exampleModel", S, A, I, expCov, expFunction, fitFunction,
                      mxData(observed=cov(tmpFrame), type="cov", numObs=dim(tmpFrame)[1]))

# Fit the model and print a summary
tmpModelOut <- mxRun(tmpModel)
summary(tmpModelOut)

---

### mxModel

Create MxModel Object

**Description**

This function creates a new MxModel object.

**Usage**

```
mxModel(model = NA, ..., manifestVars = NA, latentVars = NA,
        remove = FALSE, independent = NA, type = NA, name = NA)
```

**Arguments**

- **model**
  - This argument is either an MxModel object or a string. If 'model' is an MxModel object, then all elements of that model are placed in the resulting MxModel object. If 'model' is a string, then a new model is created with the string as its name. If 'model' is either unspecified or 'model' is a named entity, data source, or MxPath object, then a new model is created.

- **manifestVars**
  - For RAM-type models, a list of manifest variables to be included in the model.

- **latentVars**
  - For RAM-type models, a list of latent variables to be included in the model.

- **remove**
  - Logical. If TRUE, elements listed in this statement are removed from the original model. If FALSE, elements listed in this statement are added to the original model.

- **independent**
  - Logical. If TRUE then the model is evaluated independently of other models.
mxModel

**type**
character vector. The model type to assign to this model. Defaults to options("mxDefaultType"). See below for valid types

**name**
An optional character vector indicating the name of the object.

### Details

The `mxModel` function is used to create `MxModel` objects. Objects created by this function may be new, or may be modified versions of existing `MxModel` objects. By default a new `MxModel` object will be created. To create a modified version of an existing `MxModel` object, include this model in the 'model' argument.

Other *named-entities* may be added as arguments to the `mxModel` function, which are then added to or removed from the model specified in the 'model' argument. Other functions you can use to add objects to the model to this way are `mxCI`, `mxAlgebra`, `mxBounds`, `mxConstraint`, `mxData`, and `mxMatrix` objects, as well as objective functions. You can also include `MxModel` objects as sub-models of the output model, and may be estimated separately or jointly depending on shared parameters and the ‘independent’ flag discussed below. Only one `MxData` object and one objective function may be included per model, but there are no restrictions on the number of other *named-entities* included in an `mxModel` statement.

All other arguments must be named (i.e. ‘manifestVars = names’), or they will be interpreted as elements of the ellipsis list. The ‘manifestVars’ and ‘latentVars’ arguments specify the names of the manifest and latent variables, respectively, for use with the `mxPath` function. The ‘remove’ argument may be used when `mxModel` is used to create a modified version of an existing `MxMatrix` object. When ‘remove’ is set to TRUE, the listed objects are removed from the model specified in the ‘model’ argument. When ‘remove’ is set to FALSE, the listed objects are added to the model specified in the ‘model’ argument.

Model independence may be specified with the ‘independent’ argument. If a model is independent (‘independent = TRUE’), then the parameters of this model are not shared with any other model. An independent model may be estimated with no dependency on any other model. If a model is not independent (‘independent = FALSE’), then this model shares parameters with one or more other models such that these models must be jointly estimated. These dependent models must be entered as arguments in another model, so that they are simultaneously optimized.

The model type is determined by a character vector supplied to the ‘type’ argument. The type of a model is a dynamic property, ie. it is allowed to change during the lifetime of the model. To see a list of available types, use the `mxTypes` command. When a new model is created and no type is specified, the type specified by `options("mxDefaultType")` is used.

To be estimated, `MxModel` objects must include objective functions as arguments (`mxAlgebraObjective`, `mxFIMLObjective`, `mxMLObjective` or `mxRAMObjective`) and executed using the `mxRun` function. When `MxData` objects are included in models, the ‘type’ argument of these objects may require or exclude certain objective functions, or set an objective function as default.

*Named entities* in `MxModel` objects may be viewed and referenced by name using the $ symbol. For instance, for an `MxModel` named "yourModel" containing an `MxMatrix` named "yourMatrix", the contents of "yourMatrix" can be accessed as `yourModel$yourMatrix`. Slots (i.e., matrices, algebras, etc.) in an `mxMatrix` may also be referenced with the $ symbol (e.g., `yourModel$matrices` or `yourModel$algebras`). See the documentation for `Classes` and the examples in `Classes` for more information.
Value

Returns a new MxModel object. MxModel objects must include an objective function to be used as arguments in mxRun functions.

Examples

library(OpenMx)

# At the simplest, you can create an empty model, # placing it in an object, and add to it later emptyModel <- mxModel(model="IAmEmpty")

# Create a model named 'firstdraft' with one matrix 'A'
firstModel <- mxModel(model="firstdraft",
  mxMatrix(type='Full', nrow = 3, ncol = 3, name = "A"))

# Update 'firstdraft', and rename the model 'finaldraft'
finalModel <- mxModel(model=firstModel,
  mxMatrix(type='Symm', nrow = 3, ncol = 3, name = "S"),
  mxMatrix(type='Iden', nrow = 3, name = "F"),
  name= "finaldraft")

# Add data to the model from an existing data frame in object 'data'
data(twinData) # load some data
finalModel <- mxModel(model=finalModel, mxData(twinData, type='raw'))

# Two ways to view the matrix named "A" in MxModel object 'model'

finalModel$A
finalModel$matrices$A

# A working example using OpenMx Path Syntax
data(HS.ability.data) # load the data

# The manifest variables loading on each proposed latent variable Spatial <- c("visual", "cubes", "paper")
Verbal <- c("general", "paragrap", "sentence")
Math <- c("numeric", "series", "arithmet")

latents <- c("vis", "math", "text")
manifests <- c(Spatial, Math, Verbal)

HSModel <- mxModel(model="Holzinger_and_Swineford_1939", type="RAM",
                   manifestVars = manifests, # list the measured variables (boxes)
                   latentVars = latents, # list the latent variables (circles)
                   # factor loadings from latents to manifests
                   mxPath(from="vis", to=Spatial),# factor loadings
                   mxPath(from="math", to=Math), # factor loadings
                   mxPath(from="text", to=Verbal), # factor loadings

                   # Allow latent variables to covary
                   mxPath(from="vis", to="math", arrows=2, free=TRUE),
                   mxPath(from="vis", to="text", arrows=2, free=TRUE),
                   mxPath(from="math", to="text", arrows=2, free=TRUE),

                   # Allow latent variables to have variance
                   mxPath(from=latents, arrows=2, free=FALSE, values=1.0),
                   # Manifest have residual variance
                   mxPath(from=manifests, arrows=2),
                   # the data to be analysed
                   mxData(cov(HS.ability.data[,manifests]), type = "cov", numObs = 301))

fitModel <- mxRun(HSModel) # run the model
summary(fitModel) # examine the output: Fit statistics and path loadings

---

MxModel-class

MxModel Class

Description

MxModel is an S4 class. An MxModel object is a named entity.

Details

The ‘matrices’ slot contains a list of the MxMatrix objects included in the model. These objects are listed by name. Two objects may not share the same name. If a new MxMatrix is added to an MxModel object with the same name as an MxMatrix object in that model, the added version replaces the previous version. There is no imposed limit on the number of MxMatrix objects that may be added here.

The ‘algebras’ slot contains a list of the MxAlgebra objects included in the model. These objects are listed by name. Two objects may not share the same name. If a new MxAlgebra is added to an MxModel object with the same name as an MxAlgebra object in that model, the added version replaces the previous version. All MxMatrix objects referenced in the included MxAlgebra objects must be included in the ‘matrices’ slot prior to estimation. There is no imposed limit on the number of MxAlgebra objects that may be added here.
The ‘constraints’ slot contains a list of the MxConstraint objects included in the model. These objects are listed by name. Two objects may not share the same name. If a new MxConstraint is added to an MxModel object with the same name as an MxConstraint object in that model, the added version replaces the previous version. All MxMatrix objects referenced in the included MxConstraint objects must be included in the ‘matrices’ slot prior to estimation. There is no imposed limit on the number of MxConstraint objects that may be added here.

The ‘intervals’ slot contains a list of the confidence intervals requested by included MxCI objects. These objects are listed by the free parameters, MxMatrices and MxAlgebras referenced in the MxCI objects, not the list of MxCI objects themselves. If a new MxCI object is added to an MxModel object referencing one or more free parameters MxMatrices or MxAlgebras previously listed in the ‘intervals’ slot, the new confidence interval(s) replace the existing ones. All listed confidence intervals must refer to free parameters MxMatrices or MxAlgebras in the model.

The ‘latentVars’ slot contains a list of latent variable names, which may be referenced by MxPath objects. This slot defaults to ‘NA’, and is only used when the mxPath function is used.

The ‘manifestVars’ slot contains a list of latent variable names, which may be referenced by MxPath objects. This slot defaults to ‘NA’, and is only used when the mxPath function is used.

The ‘data’ slot contains an MxData object. This slot must be filled prior to execution when a fitfunction referencing data is used. Only one MxData object may be included per model, but submodels may have their own data in their own ‘data’ slots. If an MxData object is added to an MxModel which already contains an MxData object, the new object replaces the existing one.

The ‘submodels’ slot contains references to all of the MxModel objects included as submodels of this MxModel object. Models held as arguments in other models are considered to be submodels. These objects are listed by name. Two objects may not share the same name. If a new submodel is added to an MxModel object with the same name as an existing submodel, the added version replaces the previous version. When a model containing other models is executed using mxRun, all included submodels are executed as well. If the submodels are dependent on one another, they are treated as one larger model for purposes of estimation.

The ‘independent’ slot contains a logical value indicating whether or not the model is independent. If a model is independent (independent=TRUE), then the parameters of this model are not shared with any other model. An independent model may be estimated with no dependency on any other model. If a model is not independent (independent=FALSE), then this model shares parameters with one or more other models such that these models must be jointly estimated. These dependent models must be entered as submodels of another MxModel objects, so that they are simultaneously optimized.

The ‘options’ slot contains a list of options for the model. The name of each entry in the list is the option name to be used at runtime. The values in this list are the values of the optimizer options. The standard interface for updating options is through the mxOption function.

The ‘output’ slot contains a list of output added to the model by the mxRun function. Output includes parameter estimates, optimization information, model fit, and other information. If a model has not been optimized using the mxRun function, the ‘output’ slot will be ‘NULL’.

Named entities in MxModel objects may be viewed and referenced by name using the $ symbol. For instance, for an MxModel named "yourModel" containing an MxMatrix named "yourMatrix", the contents of "yourMatrix" can be accessed as yourModel$yourMatrix. Slots (i.e., matrices, algebras, etc.) in an mxMatrix may also be referenced with the $ symbol (e.g., yourModel$matrices or yourModel$algebras). See the documentation for Classes and the examples in mxModel for more information.
Objects from the Class

Objects can be created by calls of the form `mxModel()`.

Slots

- **name**: Character string. The name of the model object.
- **matrices**: List of the model's `MxMatrix` objects.
- **algebras**: List of the model's `MxAlgebra` objects.
- **constraints**: List of the model's `MxConstraint` objects.
- **intervals**: List of the model's `MxInterval` objects, requested via `mxCI()`.
- **latentVars**: "Latent variables;" object of class "MxCharOrList".
- **manifestVars**: "Manifest variables;" object of class "MxCharOrList".
- **data**: Object of class `MxData`.
- **submodels**: List of `MxModel` objects.
- **expectation**: Object of class `MxExpectation`; dictates the model’s specification.
- **fitfunction**: Object of class `MxFitFunction`; dictates the cost function to be minimized when fitting the model.
- **compute**: Object of class `MxCompute`—the model’s compute plan, which contains instructions on what the model is to compute and how to do so.
- **independent**: Logical; is the model to be run independently from other submodels?
- **options**: List of model-specific options, set by `mxOption()`.
- **output**: List of model output produced during a call to `mxRun()`.
- **runstate**: List produced by `mxRun()`, which contains the pre-run state of the model object.
- **.newobjects**: Logical; for internal use.
- **.resetdata**: Logical; for internal use.
- **.wasRun**: Logical; for internal use.
- **.modifiedSinceRun**: Logical; for internal use.
- **.version**: Object of class "package_version"; for internal use.

Methods

- `$ signature(x = "MxModel")`: Accessor. Accesses slots by slot-name. Also accesses constituent named entities, by name.
- `$<- signature(x = "MxModel")`: Assignment. Generally, this method will not allow the user to make unsafe changes to the MxModel object.
- `[[ signature(x = "MxModel")`: Accessor for constituent named entities.
- `[[<- signature(x = "MxModel")`: Assignment for a named entity.
- **names** signature(x = "MxModel")**: Returns names of slots and named entities.
- **print signature(x = "MxModel")**: "Print" method.
- **show signature(object = "MxModel")**: "Show" method.

Note that `imxInitModel()`, `imxModelBuilder()`, `imxTypeName()`, and `imxVerifyModel()` are separately documented methods for class "MxModel".
mxNormalQuantiles

Examples

showClass("MxModel")

mxNormalQuantiles mxNormalQuantiles

Description

Get quantiles from a normal distribution

Usage

mxNormalQuantiles(nBreaks, mean = 0, sd = 1)

Arguments

nBreaks    the number of thresholds, or a vector of the number of thresholds
mean      the mean of the underlying normal distribution
sd        the standard deviation of the underlying normal distribution

Value

a vector of quantiles

Examples

mxNormalQuantiles(3)
mxNormalQuantiles(3, mean=7)
mxNormalQuantiles(2, mean=1, sd=3)
mxOption

Set or Clear an Optimizer Option

Description

The function sets, shows, or clears an option that is specific to the optimizer in the back-end.

Usage

mxOption(model, key, value, reset = FALSE)

Arguments

model An MxModel object or NULL
key The name of the option.
value The value of the option.
reset If TRUE then reset all options to their defaults.

Details

mxOption is used to set, clear, or query an option (given in the ‘key’ argument) in the back-end optimizer. Valid option keys are listed below.

Use value = NULL to remove an existing option. Leaving value blank will return the current value of the option specified by ‘key’.

To reset all options to their default values, use ‘reset = TRUE’. When reset = TRUE, ‘key’ and ‘value’ are ignored.

If the ‘model’ argument is set to NULL, the default optimizer option (i.e those applying to all models by default) will be set.

To see the defaults, use getOption('mxOptions').

Before the model is submitted to the back-end, all keys and values are converted into strings using the as.character function.

The “Default optimizer” option can only be set globally (i.e., with model=NULL), and not locally (i.e., specifically to a given MxModel). Although the checkpointing options may be set globally, OpenMx’s behavior is only affected by locally set checkpointing options (that is, global checkpointing options are ignored at runtime).

Options “Gradient step size”, “Gradient iterations”, and “Function precision” have on-load global defaults of "Auto". If value "Auto" is in effect for any of these three options at runtime, then OpenMx selects a reasonable numerical value in its place. These automated numerical values are intended to (1) adjust for the limited precision of the algorithm for computing multivariate-normal probability integrals, and (2) calculate accurate numeric derivatives at the optimizer’s solution. If the user replaces "Auto" with a valid numerical value, then OpenMx uses that value as-is.

Some options only affect certain optimizers. Currently, options “Gradient algorithm” and “Gradient iterations” are ignored by all optimizers other than SLSQP. Also, currently option “Analytic Gradients” only affects SLSQP and NPSOL. Option “Gradient step size” is used slightly differently
by SLSQP and CSOLNP, and is ignored by NPSOL (see `mxComputeGradientDescent()` for details). If the MxModel contains `MxConstraints`, OpenMx’s interface to NPSOL scales “Feasibility tolerance” by multiplying it by 0.02 and dividing it by 0.05 before passing it to NPSOL; if there are no MxConstraints, OpenMx passes NPSOL a hardcoded value of 1e-5. Note that NPSOL’s criterion for returning a status code of 0 versus 1 for a given solution depends partly on “Optimality tolerance”.

For a block of \( n \) ordinal variables, the maximum number of integration points that OpenMx may use to calculate multivariate-normal probability integrals is given by \( \text{mvnMaxPointsA} + \text{mvnMaxPointsB}n + \text{mvnMaxPointsC}n^2 \).

The maximum number of major iterations (the option “Major iterations”) for optimization for NPSOL can be specified either by using a numeric value (such as 50, 1000, etc) or by specifying a user-defined function. The user-defined function should accept two arguments as input, the number of parameters and the number of constraints, and return a numeric value as output.

**OpenMx options**

- **Calculate Hessian** [Yes | No] calculate the Hessian explicitly after optimization.
- **Standard Errors** [Yes | No] return standard error estimates from the explicitly calculate hessian.
- **Default optimizer** [NPSOL | SLSQP | CSOLNP] the gradient-descent optimizer to use
- **Number of Threads** [0|1|2|...|10|...] number of threads used for optimization. Default value is taken from the environment variable OMP_NUM_THREADS or, if that is not set, 2.
- **Feasibility tolerance** \( r \) the maximum acceptable absolute violations in linear and nonlinear constraints.
- **Optimality tolerance** \( r \) the accuracy with which the final iterate approximates a solution to the optimization problem; roughly, the number of reliable significant figures that the fit function value should have at the solution.
- **Gradient algorithm** see list finite difference method, either ‘forward’ or ‘central’.
- **Gradient iterations** 1:4 the number of Richardson extrapolation iterations
- **Gradient step size** \( r \) amount of change made to free parameters when numerically calculating gradient
- **Analytic Gradients** [Yes | No] should the optimizer use analytic gradients (if available)?
- **loglikelihoodScale** \( i \) factor by which the loglikelihood is scaled.
- **Parallel diagnostics** [Yes | No] whether to issue diagnostic messages about use of multiple threads
- **Nudge zero starts** [TRUE | FALSE] Should OpenMx "nudge" starting values of zero to 0.1 at runtime?
- **Status OK** character vector Status codes that are considered to indicate a successful optimization

**NPSOL-specific options**

- **Nolist** this option suppresses printing of the options
- **Print level** \( i \) the value of \( i \) controls the amount of printout produced by the major iterations
- **Minor print level** \( i \) the value of \( i \) controls the amount of printout produced by the minor iterations
- **Print file** \( i \) for \( i > 0 \) a full log is sent to the file with logical unit number \( i \).
- **Summary file** \( i \) for \( i > 0 \) a brief log will be output to file \( i \).
- **Function precision** \( r \) a measure of accuracy with which the fit function and constraint functions can be computed.
- **Infinite bound size** \( r \) if \( r > 0 \) defines the "infinite" bound bigbnd.
- **Major iterations** \( i \) or a function the maximum number of major iterations before termination.
- **Verify level** [-1:3 | Yes | No] see NPSOL manual.
- **Line search tolerance** \( r \) controls the accuracy with which a step is taken.
- **Derivative level** [0-3] see NPSOL manual.
- **Hessian** [Yes | No] return the Hessian (Yes) or the transformed Hessian (No).
- **Step Limit** \( r \) maximum change in free parameters at first step of linesearch.

**Checkpointing options**
**mxOption**

**Value**

If a model is provided, it is returned with the optimizer option either set or cleared. If value is empty, the current value is returned.

**References**

The OpenMx User's guide can be found at http://openmx.ssri.psu.edu/documentation.

**See Also**

See `mxModel()`, as almost all uses of `mxOption()` are via an `mxModel` whose options are set or cleared. See `mxComputeGradientDescent()` for details on how different optimizers are affected by different options. See `as.statusCode` for information about the Status OK option.

**Examples**

```r
# set the Number of Threads (cores to use)
mxOption(NULL, "Number of Threads", parallel::detectCores() - 1)

testModel <- mxModel(model = "testModel") # make a model to use for example
testModel$options # show the model options (none yet)
options()$mxOptions # list all mxOptions (global settings)
```
testModel <- mxOption(testModel, "Function precision", 1e-5) # set precision
testModel <- mxOption(testModel, "Function precision", NULL) # clear precision
# N.B. This is model-specific precision (defaults to global setting)

# may optimize for speed
# at cost of not getting standard errors
testModel <- mxOption(testModel, "Calculate Hessian", "No")
testModel <- mxOption(testModel, "Standard Errors", "No")

testModel$options # see the list of options you set

mxParametricBootstrap

Assess whether potential parameters should be freed using parametric bootstrap

Description

Data is simulated from ‘nullModel’. The parameters named by ‘labels’ are freed to obtain the alternative model. The alternative model is fit against each simulated data set.

Usage

mxParametricBootstrap(nullModel, labels, alternative=c("two.sided", "greater", "less"), ..., alpha=0.05, correction=p.adjust.methods, previousRun=NULL, replications=400, checkHess=FALSE, signif.stars = getOption("show.signif.stars"))

Arguments

nullModel The model specifying the null distribution
labels A character vector of parameters to free to obtain the alternative model
alternative a character string specifying the alternative hypothesis
... Not used. Forces remaining arguments to be specified by name.
alpha The false positive rate
correction How to adjust the p values for multiple tests.
replications The number of resampling replications. If available, replications from prior invocation will be reused.
previousRun Results to re-use from a previous bootstrap.
checkHess Whether to approximate the Hessian in each replication
signif.stars logical. If TRUE, ‘significance stars’ are printed for each coefficient.
Details

When the model has a default compute plan and ‘checkHess’ is kept at FALSE then the Hessian will not be approximated or checked. On the other hand, ‘checkHess’ is TRUE then the Hessian will be approximated by finite differences. This procedure is of some value because it can be informative to check whether the Hessian is positive definite (see mxComputeHessianQuality). However, approximating the Hessian is often costly in terms of CPU time. For bootstrapping, the parameter estimates derived from the resampled data are typically of primary interest.

Value

A data frame is returned containing the test results. Details of the bootstrap replications are stored in the ‘bootData’ attribute on the data frame.

Examples

library(OpenMx)
data(demoOneFactor)
manifests <- names(demoOneFactor)
lats <- c("G")

base <- mxModel(
    "OneFactorCov", type="RAM",
    manifestVars = manifests,
    latentVars = lats,
    mxPath(from=lats, to=manifests, values=0, free=FALSE, labels=paste0("l",1:length(manifests))),
    mxPath(from=manifests, arrows=2, values=rlnorm(length(manifests)), lbound=.01),
    mxPath(from=lats, arrows=2, free=FALSE, values=1.0),
    mxPath(from = 'one', to = manifests, values=0, free=TRUE, labels=paste0("m",1:length(manifests))),
    mxData(demoOneFactor, type="raw"))

base <- mxRun(base)

# use more replications, 8 is for demonstration purpose only
mxParametricBootstrap(base, paste0("l", 1:length(manifests)),
    "two.sided", replications=8)

mxPath

Create List of Paths

Description

This function creates a list of paths.

Usage

mxPath(from, to = NA, connect = c("single", "all.pairs", "unique.pairs", "all.bivariate", "unique.bivariate"), arrows = 1,
free = TRUE, values = NA, labels = NA,
lbound = NA, ubound = NA, ..., joinKey = as.character(NA))
Arguments

from character vector. These are the sources of the new paths.
to character vector. These are the sinks of the new paths.
connect String. Specifies the type of source to sink connection: "single", "all.pairs", "all.bivariate", "unique.pairs", "unique.bivariate". Default value is "single".
arrows numeric value. Must be either 1 (for single-headed) or 2 (for double-headed arrows).
free boolean vector. Indicates whether paths are free or fixed.
values numeric vector. The starting values of the parameters.
labels character vector. The names of the paths.
lbound numeric vector. The lower bounds of free parameters.
ubound numeric vector. The upper bounds of free parameters.
... Not used. Allows OpenMx to catch the use of the deprecated ‘all’ argument.
joinKey character vector. The name of the foreign key to join against some other model to create a cross model path (regression or factor loading).

Details

The mxPath function creates MxPath objects. These consist of a list of paths describing the relationships between variables in a model using the RAM modeling approach (McArdle and MacDonald, 1984). Variables are referenced by name, and these names must appear in the ‘manifestVar’ and ‘latentVar’ arguments of the mxModel function.

Paths are specified as going "from" one variable (or set of variables) "to" another variable or set of variables using the ‘from’ and ‘to’ arguments, respectively. If ‘to’ is left empty, it will be set to the value of ‘from’.

‘connect’ has five possible connection types: "single", "all.pairs", "all.bivariate", "unique.pairs", "unique.bivariate". The default value is "single". Assuming the values c(‘a’,’b’,’c’) for the ‘to’ and ‘from’ fields the paths produced by each connection type are as follows:

"all.pairs": (a,a), (a,b), (a,c), (b,a), (b,b), (b,c), (c,a), (c,b), (c,c).
"unique.pairs": (a,a), (a,b), (a,c), (b,b), (b,c), (c,c).
"all.bivariate": (a,b), (a,c), (b,a), (b,c), (c,a), (c,b).
"unique.bivariate": (a,b), (a,c), (b,c).
"single": (a,a), (b,b), (c,c).

Multiple variables may be input as a vector of variable names. If the ‘connect’ argument is set to "single", then paths are created going from each entry in the ‘from’ vector to the corresponding entry in the ‘to’ vector. If the ‘to’ and ‘from’ vectors are of different lengths when the ‘connect’ argument is set to "single", the shorter vector is repeated to make the vectors of equal length.

The ‘free’ argument specifies whether the paths created by the mxPath function are free or fixed parameters. This argument may take either TRUE for free parameters, FALSE for fixed parameters, or a vector of TRUEs and FALSEs to be applied in order to the created paths.
The ‘arrows’ argument specifies the type of paths created. A value of 1 indicates a one-headed arrow representing regression. This path represents a regression of the ‘to’ variable on the ‘from’ variable, such that the arrow points to the ‘to’ variable in a path diagram. A value of 2 indicates a two-headed arrow, representing a covariance or variance. If multiple paths are created in the same `mxPath` function, then the ‘arrows’ argument may take a vector of 1s and 2s to be applied to the set of created paths.

The ‘values’ is a numeric vectors containing the starting values of the created paths. ‘values’ gives a starting value for estimation. The ‘labels’ argument specifies the names of the resulting `MxPath` object. The ‘lbound’ and ‘ubound’ arguments specify lower and upper bounds for the created paths.

Value

Returns a list of paths.

Note

The previous implementation of ‘all’ had unsafe features. Its use is now deprecated, and has been replaced by the new mechanism ‘connect’ which supports safe and controlled generation of desired combinations of paths.

**mxRAMObjective**

*DEPRECATED: Create MxRAMObjective Object*

---

**Description**

**WARNING:** Objective functions have been deprecated as of OpenMx 2.0.

Please use `mxExpectationRAM()` and `mxFitFunctionML()` instead. As a temporary workaround, `mxRAMObjective` returns a list containing an `MxExpectationNormal` object and an `MxFitFunctionML` object.

All occurrences of

```
mxRAMObjective(A, S, F, M = NA, dimnames = NA, thresholds = NA, threshnames = dimnames)
```

Should be changed to

```
mxExpectationRAM(A, S, F, M = NA, dimnames = NA, thresholds = NA, threshnames = dimnames) mxFitFunctionML(vector = FALSE)
```
mxRAMObjective

Arguments

- **A**: A character string indicating the name of the 'A' matrix.
- **S**: A character string indicating the name of the 'S' matrix.
- **F**: A character string indicating the name of the 'F' matrix.
- **M**: An optional character string indicating the name of the 'M' matrix.
- **dimnames**: An optional character vector to be assigned to the column names of the 'F' and 'M' matrices.
- **thresholds**: An optional character string indicating the name of the thresholds matrix.
- **vector**: A logical value indicating whether the objective function result is the likelihood vector.
- **threshnames**: An optional character vector to be assigned to the column names of the thresholds matrix.

Details

NOTE: THIS DESCRIPTION IS DEPRECATED. Please change to using `mxExpectationRAM` and `mxFitFunctionML` as shown in the example below.

Objective functions were functions for which free parameter values are chosen such that the value of the objective function was minimized. The mxRAMObjective provided maximum likelihood estimates of free parameters in a model of the covariance of a given MxData object. This model is defined by reticular action modeling (McArdle and McDonald, 1984). The 'A', 'S', and 'F' arguments must refer to MxMatrix objects with the associated properties of the A, S, and F matrices in the RAM modeling approach.

The 'dimnames' argument takes an optional character vector. If this argument is not a single NA, then this vector be assigned to be the column names of the 'F' matrix and optionally to the 'M' matrix, if the 'M' matrix exists.

The 'A' argument refers to the A or asymmetric matrix in the RAM approach. This matrix consists of all of the asymmetric paths (one-headed arrows) in the model. A free parameter in any row and column describes a regression of the variable represented by that row regressed on the variable represented in that column.

The 'S' argument refers to the S or symmetric matrix in the RAM approach, and as such must be square. This matrix consists of all of the symmetric paths (two-headed arrows) in the model. A free parameter in any row and column describes a covariance between the variable represented by that row and the variable represented by that column. Variances are covariances between any variable at itself, which occur on the diagonal of the specified matrix.

The 'F' argument refers to the F or filter matrix in the RAM approach. If no latent variables are included in the model (i.e., the A and S matrices are of both of the same dimension as the data matrix), then the 'F' should refer to an identity matrix. If latent variables are included (i.e., the A and S matrices are not of the same dimension as the data matrix), then the 'F' argument should consist of a horizontal adhesion of an identity matrix and a matrix of zeros.

The 'M' argument refers to the M or means matrix in the RAM approach. It is a 1 x n matrix, where n is the number of manifest variables + the number of latent variables. The M matrix must be specified if either the mxData type is "cov" or "cor" and a means vector is provided, or if the mxData type is "raw". Otherwise the M matrix is ignored.
The MxMatrix objects included as arguments may be of any type, but should have the properties described above. The mxRAMObjective will not return an error for incorrect specification, but incorrect specification will likely lead to estimation problems or errors in the mxRun function.

mxRAMObjective evaluates with respect to an MxData object. The MxData object need not be referenced in the mxRAMObjective function, but must be included in the MxModel object. mxRAMObjective requires that the ‘type’ argument in the associated MxData object be equal to ‘cov’ or ‘cor’.

To evaluate, place MxRAMObjective objects, the mxData object for which the expected covariance approximates, referenced MxAlgebra and MxMatrix objects, and optional MxBounds and MxConstraint objects in an MxModel object. This model may then be evaluated using the mxRun function. The results of the optimization can be found in the ‘output’ slot of the resulting model, and may be obtained using the mxEval function.

Value

Returns a list containing an MxExpectationRAM object and an MxFitFunctionML object.

Examples

# Create and fit a model using mxMatrix, mxAlgebra, # mxExpectationNormal, and mxFitFunctionML
library(OpenMx)
# Simulate some data
x=rnorm(1000, mean=0, sd=1)
y= 0.5*x + rnorm(1000, mean=0, sd=1)
tmpFrame <- data.frame(x, y)
tmpNames <- names(tmpFrame)
# Define the matrices
matrixS <- mxMatrix(type = "Full", nrow = 2, ncol = 2, values=c(1,0,0,1),
                  free=c(TRUE,FALSE,FALSE,TRUE), labels=c("Vx", NA, NA, "Vy"),
                  name = "S")
matrixA <- mxMatrix(type = "Full", nrow = 2, ncol = 2, values=c(0,1,0,0),
                  free=c(FALSE,TRUE,FALSE,FALSE), labels=c(NA, "b", NA, NA),
                  name = "A")
matrixF <- mxMatrix(type="Iden", nrow=2, ncol=2, name="F")
matrixM <- mxMatrix(type = "Full", nrow = 1, ncol = 2, values=c(0,0),

```r
free=c(TRUE,TRUE), labels=c("Mx", "My"), name = "M")

# Define the expectation
expFunction <- mxExpectationRAM(M="M", dimnames = tmpNames)

# Choose a fit function
fitFunction <- mxFitFunctionML()

# Define the model
tmpModel <- mxModel(model="exampleRAMModel",
                     matrixA, matrixS, matrixF, matrixM,
                     expFunction, fitFunction,
                     mxData( observed= cov(tmpFrame), type="cov", numObs=nrow(tmpFrame),
                     means = colMeans(tmpFrame)) )

# Fit the model and print a summary
tmpModelOut <- mxRun(tmpModel)
summary(tmpModelOut)
```

---

### mxRename

**Rename MxModel or a Submodel**

**Description**

This function renames either the top model or a submodel to a new name. All internal references to the old model name are replaced with references to the new name.

**Usage**

```r
mxRename(model, newname, oldname = NA)
```

**Arguments**

- `model`: a MxModel object.
- `newname`: the new name of the model.
- `oldname`: the name of the target model to rename. If NA then rename top model.

**Value**

Return a `mxModel` object with the target model renamed.

**References**

The OpenMx User's guide can be found at http://openmx.ssri.psu.edu/documentation.
Examples

library(OpenMx)

# create two empty models
modelA <- mxModel(model='modelA')
modelB <- mxModel(model='modelB')

# create a parent model with two submodels
modelC <- mxModel(model='modelC', modelA, modelB)

# Rename modelC to model1
model1 <- mxRename(modelC, 'model1')

# Rename submodel modelB to model2
model1 <- mxRename(model1, oldname = 'modelB', newname = 'model2')

model1

mxRestore

Description

The function loads the last saved state from a checkpoint file.

Usage

mxRestore(model, chkpt.directory = ".", chkpt.prefix = "", line=NULL, strict=FALSE)

Arguments

model MxModel object to be loaded.
chkpt.directory character. Directory where the checkpoint file is located.
chkpt.prefix character. Prefix of the checkpoint file.
line integer. Which line from the checkpoint file to restore (defaults to the last line)
strict logical. Require that the checkpoint name and model name match.

Details

In general, the arguments ‘chkpt.directory’ and ‘chkpt.prefix’ should be identical to the mxOption: ‘Checkpoint Directory’ and ‘Checkpoint Prefix’ that were specified on the model before execution. Alternatively, the checkpoint file can be manually loaded as a data.frame in R. Use read.table with the options header=TRUE, sep="\t", stringsAsFactors=FALSE, check.names=FALSE.
Value

Returns an MxModel object with free parameters updated to the last saved values. When ‘line’ is provided, the MxModel is updated to the values on that line within the checkpoint file.

References

The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.

Examples

library(OpenMx)

# Simulate some data
x=rnorm(1000, mean=0, sd=1)
y= 0.5*x + rnorm(1000, mean=0, sd=1)
tmpFrame <- data.frame(x, y)
tmpNames <- names(tmpFrame)

# Create a model that includes an expected covariance matrix,
# an expectation function, a fit function, and an observed covariance matrix

data <- mxData(cov(tmpFrame), type="cov", numObs = 1000)
expCov <- mxMatrix(type="Symm", nrow=2, ncol=2, values=c(.2,.1,.2), free=TRUE, name="expCov")
expFunction <- mxExpectationNormal(covariance="expCov", dimnames=tmpNames)
fitFunction <- mxFitFunctionML()
testModel <- mxModel(model="testModel", expCov, data, expFunction, fitFunction)

# Use mxRun to optimize the free parameters in the expected covariance matrix
modelOut <- mxRun(testModel, checkpoint = TRUE)
modelOut$expCov

# Use mxRestore to load the last checkpoint saved state of the model
modelRestore <- mxRestore(testModel)
modelRestore$expCov

mxRObjective

DEPRECATED: Create MxRObjective Object

Description

WARNING: Objective functions have been deprecated as of OpenMx 2.0.
Please use mxFitFunctionR() instead. As a temporary workaround, mxRObjective returns a list containing a NULL MxExpectation object and an MxFitFunctionR object.
All occurrences of
mxRObjective(fitfun, ...)

Should be changed to
mxFitFunctionR(fitfun, ...)

Arguments

objfun A function that accepts two arguments.

... The initial state information to the objective function.

Details

NOTE: THIS DESCRIPTION IS DEPRECATED. Please change to using mxExpectationNormal and mxFitFunctionML as shown in the example below.

The fitfun argument must be a function that accepts two arguments. The first argument is the mxModel that should be evaluated, and the second argument is some persistent state information that can be stored between one iteration of optimization to the next iteration. It is valid for the function to simply ignore the second argument.

The function must return either a single numeric value, or a list of exactly two elements. If the function returns a list, the first argument must be a single numeric value and the second element will be the new persistent state information to be passed into this function at the next iteration. The single numeric value will be used by the optimizer to perform optimization.

The initial default value for the persistent state information is NA.

Throwing an exception (via stop) from inside fitfun may result in unpredictable behavior. You may want to wrap your code in tryCatch while experimenting.

Value

Returns a list containing a NULL mxExpectation object and an MxFitFunctionR object.

References

The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.

Examples

# Create and fit a model using mxFitFunctionR

library(OpenMx)

A <- mxMatrix(nrow = 2, ncol = 2, values = c(1:4), free = TRUE, name = 'A')
squared <- function(x) { x ^ 2 }

# Define the objective function in R

objFunction <- function(model, state) {
  values <- model$A$values
  return(squared(values[1,1] - 4) + squared(values[1,2] - 3) +}
mxRowObjective

squared(values[2,1] - 2) + squared(values[2,2] - 1))

# Define the expectation function
fitFunction <- mxFitFunctionR(objFunction)

# Define the model
tmpModel <- mxModel(model="exampleModel", A, fitFunction)

# Fit the model and print a summary
tmpModelOut <- mxRun(tmpModel)
summary(tmpModelOut)

mxRowObjective

DEPRECATED: Create MxRowObjective Object

Description

WARNING: Objective functions have been deprecated as of OpenMx 2.0.
Please use mxFitFunctionRow() instead. As a temporary workaround, mxRowObjective returns a list containing a NULL MxExpectation object and an MxFitFunctionRow object.

All occurrences of
mxRowObjective(rowAlgebra, reduceAlgebra, dimnames, rowResults = "rowResults", filteredDataRow = "filteredDataRow", existenceVector = "existenceVector")
Should be changed to
mxFitFunctionRow(rowAlgebra, reduceAlgebra, dimnames, rowResults = "rowResults", filteredDataRow = "filteredDataRow", existenceVector = "existenceVector")

Arguments

rowAlgebra A character string indicating the name of the algebra to be evaluated row-wise.
reduceAlgebra A character string indicating the name of the algebra that collapses the row results into a single number which is then optimized.
dimnames A character vector of names corresponding to columns be extracted from the data set.
rowResults The name of the auto-generated "rowResults" matrix. See details.
filteredDataRow The name of the auto-generated "filteredDataRow" matrix. See details.
existenceVector The name of the auto-generated "existenceVector" matrix. See details.
Details

Objective functions are functions for which free parameter values are chosen such that the value of the objective function is minimized. The mxRowObjective function evaluates a user-defined MxAlgebra object called the ‘rowAlgebra’ in a row-wise fashion. It then stores results of the row-wise evaluation in another MxAlgebra object called the ‘rowResults’. Finally, the mxRowObjective function collapses the row results into a single number which is then used for optimization. The MxAlgebra object named by the ‘reduceAlgebra’ collapses the row results into a single number.

The ‘filteredDataRow’ is populated in a row-by-row fashion with all the non-missing data from the current row. You cannot assume that the length of the filteredDataRow matrix remains constant (unless you have no missing data). The ‘existenceVector’ is populated in a row-by-row fashion with a value of 1.0 in column j if a non-missing value is present in the data set in column j, and a value of 0.0 otherwise. Use the functions omxSelectRows, omxSelectCols, and omxSelectRowsAndCols to shrink other matrices so that their dimensions will be conformable to the size of ‘filteredDataRow’.

Value

Please use mxFitFunctionRow() instead. As a temporary workaround, mxRowObjective returns a list containing a NULL MxExpectation object and an MxFitFunctionRow object.

References

The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.

Examples

# Model that adds two data columns row-wise, then sums that column
# Notice no optimization is performed here.

library(OpenMx)

xdat <- data.frame(a=rnorm(10), b=1:10) # Make data set
amod <- mxModel(model="example1",
    mxData(observed=xdat, type="raw"),
    mxAlgebra(sum(filteredDataRow), name = 'rowAlgebra'),
    mxAlgebra(sum(rowResults), name = 'reduceAlgebra'),
    mxFitFunctionRow(
        rowAlgebra='rowAlgebra',
        reduceAlgebra='reduceAlgebra',
        dimnames=c('a','b'))
)
amodOut <- mxRun(amod)
mxEval(rowResults, model=amodOut)
mxEval(reduceAlgebra, model=amodOut)

# Model that find the parameter that minimizes the sum of the
# squared difference between the parameter and a data row.

bmod <- mxModel(model="example2",
    mxData(observed=xdat, type="raw"),
    mxMatrix(values=.75, ncol=1, nrow=1, free=TRUE, name='B'),

mxRun

```r
mxAlgebra((filteredDataRow - B) ^ 2, name='rowAlgebra'),
mxAlgebra(sum(rowResults), name='reduceAlgebra'),
mxFitFunctionRow(
  rowAlgebra='rowAlgebra',
  reduceAlgebra='reduceAlgebra',
  dimnames=c('a'))
)
bmodOut <- mxRun(bmod)
mxEval(B, model=bmodOut)
mxEval(reduceAlgebra, model=bmodOut)
mxEval(rowResults, model=bmodOut)
```

---

**mxRun**

*Send a Model to the Optimizer*

**Description**

This function begins optimization on the top-level model.

**Usage**

```r
mxRun(model, ..., intervals = NULL, silent = FALSE, suppressWarnings = FALSE,
      unsafe = FALSE, checkpoint = FALSE, useSocket = FALSE, onlyFrontend = FALSE,
      useOptimizer = TRUE)
```

**Arguments**

- `model` A `MxModel` object to be optimized.
- `...` Not used. Forces remaining arguments to be specified by name.
- `intervals` A boolean indicating whether to compute the specified confidence intervals.
- `silent` A boolean indicating whether to print status to terminal.
- `suppressWarnings` A boolean indicating whether to suppress warnings.
- `unsafe` A boolean indicating whether to ignore errors.
- `checkpoint` A boolean indicating whether to periodically write parameter values to a file.
- `useSocket` A boolean indicating whether to periodically write parameter values to a socket.
- `onlyFrontend` A boolean indicating whether to run only front-end model transformations.
- `useOptimizer` A boolean indicating whether to run only the log-likelihood of the current free parameter values but not move any of the free parameters.
**Details**

The mxRun function is used to optimize free parameters in MxModel objects based on an expectation function and fit function. MxModel objects included in the mxRun function must include an appropriate expectation and fit functions.

If the 'silent' flag is TRUE, then model execution will not print any status messages to the terminal.

If the 'suppressWarnings' flag is TRUE, then model execution will not issue a warning if NPSOL returns a non-zero status code.

If the 'unsafe' flag is TRUE, then any error conditions will throw a warning instead of an error. It is strongly recommended to use this feature only for debugging purposes.

Free parameters are estimated or updated based on the expectation and fit functions. These estimated values, along with estimation information and model fit, can be found in the 'output' slot of MxModel objects after mxRun has been used.

If a model is dependent on or shares parameters with another model, both models must be included as arguments in another MxModel object. This top-level MxModel object must include expectation and fit functions in both submodels, as well as an additional fit function describing how the results of the first two should be combined.

**Value**

Returns an MxModel object with free parameters updated to their final values. The return value contains an "output" slot with the results of optimization.

**References**

The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.

**Examples**

```r
# Create and run the 1-factor CFA on the openmx.psyc.virginia.edu front page
library(OpenMx)
data(demoOneFactor) # load the demoOneFactor dataframe

manifests <- names(demoOneFactor) # set the manifest to the 5 demo variables
latents <- c("G") # define 1 latent variable
model <- mxModel(model="One Factor", type="RAM",
  manifestVars = manifests,
  latentVars = latents,
  mxPath(from=latents, to=manifests, labels=paste("b", 1:5, sep="")),
  mxPath(from=manifests, arrows=2, labels=paste("u", 1:5, sep="")),
  mxPath(from=latents , arrows=2, free=FALSE, values=1.0),
  mxData(cov(demoOneFactor), type="cov", numObs=500)
)
model <- mxRun(model) # Run the model, returning the result into model
summary(model) # Show summary of the fitted model
```
**Description**

The function saves the last state of a model to a checkpoint file.

**Usage**

```r
mxSave(model, chkpt.directory = ".", chkpt.prefix = "")
```

**Arguments**

- `model`: MxModel object to be loaded.
- `chkpt.directory`: character. Directory where the checkpoint file is located.

**Details**

In general, the arguments 'chkpt.directory' and 'chkpt.prefix' should be identical to the `mxOption`: ‘Checkpoint Directory’ and ‘Checkpoint Prefix’ that were specified on the model before execution.

Alternatively, the checkpoint file can be manually loaded as a data.frame in R. Use `read.table` with the options `header=TRUE`, `sep="\t"`, `stringsAsFactors=FALSE`, `check.names=FALSE`.

**Value**

Returns a logical indicating the success of writing the checkpoint file to the checkpoint directory.

**References**

The OpenMx User's guide can be found at http://openmx.ssri.psu.edu/documentation.

**Examples**

```r
library(OpenMx)

# Simulate some data
x=rnorm(1000, mean=0, sd=1)
y= 0.5*x + rnorm(1000, mean=0, sd=1)
tmpFrame <- data.frame(x, y)
tmpNames <- names(tmpFrame)

# Create a model that includes an expected covariance matrix,
# an expectation function, a fit function, and an observed covariance matrix
```
```r
data <- mxData(cov(tmpFrame), type="cov", numObs = 1000)
expCov <- mxMatrix(type="Symm", nrow=2, ncol=2, values=c(.2,.1,.2), free=TRUE, name="expCov")
expFunction <- mxExpectationNormal(covariance="expCov", dimnames=tmpNames)
fitFunction <- mxFitFunctionML()
testModel <- mxModel(model="testModel", expCov, data, expFunction, fitFunction)

#Use mxRun to optimize the free parameters in the expected covariance matrix
modelOut <- mxRun(testModel)
modelOut$expCov

# Save the ending state of modelOut in a checkpoint file
mxSave(modelOut)

# Restore the saved model from the checkpoint file
modelSaved <- mxRestore(testModel)
modelSaved$expCov

# Imagine how much time you saved by not having to re-run the
# model that took hours or days to run.
```

---

**Description**

This function allows you to obtain standard errors for arbitrary expressions, named entities, and algebras.

**Usage**

```r
mxSE(x, model, details = FALSE, cov, ...)
```

**Arguments**

- `x`  
  the parameter to get SEs on (reference or expression)
- `model`  
  the `mxModel` to use.
- `details`  
  logical. Whether to provide further details, e.g. the full sampling covariance matrix of `x`.
- `cov`  
  optional matrix of covariances among the free parameters. If missing, the inverse Hessian from the fitted model is used.
- `...`  
  further named arguments passed to `mxEval`

**Details**

`x` can be the name of an algebra, a bracket address, named entity or arbitrary expression. It is a frontend-only file that works much like `mxEval`. When the `details` argument is TRUE, the full sampling covariance matrix of `x` is also returned as part of a list. The square root of the diagonals of this sampling covariance matrix are the standard errors.
When supplying the `cov` argument, take care that the free parameter covariance matrix is given, not the information matrix. These two are inverses of one another.

**Value**

SE value(s) returned as a matrix when `details` is `FALSE`. When `details` is `TRUE`, a list of the SE value(s) and the full sampling covariance matrix.

**References**

**See Also**

- `mxCI`

**Examples**

```r
library(OpenMx)
data(demoOneFactor)
# = Make and run a 1-factor CFA =
# = Make and run the model! =

latents = c("G") # the latent factor
manifests = names(demoOneFactor) # manifest variables to be modeled
m1 <- mxModel("One Factor", type = "RAM",
manifestVars = manifests, latentVars = latents,
mxPath(from = latents, to = manifests, labels=paste0('lambda', 1:5)),
mxPath(from = manifests, arrows = 2),
mxPath(from = latents, arrows = 2, free = FALSE, values = 1),
mxData(cov(demoOneFactor), type = "cov", numObs = 500)
)m1 = mxRun(m1)
mxSE(lambda5, model = m1)
mxSE(lambda1^2, model = m1)
```

**Description**

Reset global options to the default

**Usage**

`mxSetDefaultOptions()`
**mxSimplify2Array**  
*Like simplify2array but works with vectors of different lengths*

**Description**

Vectors are filled column-by-column into a matrix. Shorter vectors are padded with NAs to fill whole columns.

**Usage**

mxSimplify2Array(x, higher = FALSE)

**Arguments**

- **x** a list of vectors
- **higher** whether to produce a higher rank array (defaults to FALSE)

**Examples**

```r
v1 <- 1:3
v2 <- 4:5
v3 <- 6:10
mxSimplify2Array(list(v1,v2,v3))
```

```
# [,1] [,2] [,3]
# [1,] 1 4 6
# [2,] 2 5 7
# [3,] 3 NA 8
# [4,] NA NA 9
# [5,] NA NA 10
```

**mxStandardizeRAMpaths**  
*Standardize RAM models’ path coefficients*

**Description**

Provides a dataframe containing the standardized values of all nonzero path coefficients appearing in the A and S matrices of models that use RAM expectation (either of type="RAM" or containing an explicit mxExpectationRAM() statement). These standardized values are what the path coefficients would be if all variables in the analysis – both manifest and latent – were standardized to unit variance. Can optionally include asymptotic standard errors for those standardized coefficients, computed via the delta method. Not intended for use with models that contain definition variables.

**Usage**

mxStandardizeRAMpaths(model, SE=FALSE, cov=NULL)
Arguments

model

An `mxModel` object, that either uses RAM expectation or contains at least one submodel that does.

SE

Logical. Should standard errors be included with the standardized point estimates? Defaults to `FALSE`. Certain conditions are required for use of `SE=TRUE`; see "Details" below.

cov

A repeated-sampling covariance matrix for the free-parameter estimates–say, from the robust "sandwich estimator," or from bootstrapping–used to calculate SEs for the standardized path coefficients. Defaults to `NULL`, in which case twice the inverse of the Hessian matrix at the ML solution is used. See below for details concerning concerning cases when `model` contains independent RAM submodels.

Details

Matrix A contains the Asymmetric paths, i.e. the single-headed arrows. Matrix S contains the Symmetric paths, i.e. the double-headed arrows. The function will work even if `mxMatrix` objects named "A" and "S" are absent from the model, since it identifies which matrices in the model have been assigned the roles of A and S in the `mxExpectationRAM` statement. Note that, in models of type="RAM", the necessary matrices and expectation statement are automatically assembled from the `mxPath` objects.

If `model` contains any submodels with independent=TRUE that use RAM expectation, `mxStandardizeRAMpaths()` automatically applies itself recursively over those submodels. However, if a non-NULL matrix has been supplied for argument cov, that matrix is only used for the "container" model, and is not passed as argument to the recursive calls of the function. To provide a covariance matrix for calculating SEs in an independent submodel, use `mxStandardizeRAMpaths()` directly on that submodel.

Use of `SE=TRUE` requires that package `numDeriv` be installed. It also requires that model contain no `mxConstraint` statements. Finally, if `cov=NULL`, it requires model to have a nonempty hessian element in its output slot. There are three common reasons why the latter condition may not be met. First, the model may not have been run yet, i.e. it was not output by `mxRun()`. Second, `mxOption "Hessian"` might be set to "No". Third, computing the Hessian matrix might possibly have been skipped per a user-defined `mxCompute*` statement (if any are present in the model). If `model` contains RAM-expectation submodels with independent=TRUE, these conditions are checked separately for each such submodel.

In any event, using these standard errors for hypothesis-testing or forming confidence intervals is not generally advised. Instead, it is considered best practice to conduct likelihood-ratio tests or compute likelihood-based confidence intervals (from `mxCI()`), as in examples below.

The user should note that `mxStandardizeRAMpaths()` only cares whether an element of A or S is nonzero, and not whether it is a fixed or free parameter. So, for instance, if the function is used on a model not yet run, any free parameters in A or S initialized at zero will not appear in the function’s output.

The user is warned to interpret the output of `mxStandardizeRAMpaths()` cautiously if any elements of A or S depend upon "definition variables" (you have definition variables in your model if the labels of any `MxPath` or `MxMatrix` begin with "data."). Typically, either `mxStandardizeRAMpaths()`’s results will be valid only for the first row of the raw dataset (and any rows identical to it), or some of the standardized coefficients will be incorrectly reported as zero.
Value

If argument model is a single-group model that uses RAM expectation, then mxStandardizeRAMpaths() returns a dataframe, with one row for each nonzero path coefficient in A and S, and with the following columns:

- **name**: Character strings that uniquely identify each nonzero path coefficient in terms of the model name, the matrix ("A" or "S"), the row number, and the column number.
- **label**: Character labels for those path coefficients that are labeled elements of an mxMatrix object, and NA for those that are not. Note that path coefficients having the same label (and therefore the same UNstandardized value) can have different standardized values, and therefore the same label may appear more than once in this dataframe.
- **matrix**: Character strings of "A" or "S", depending on which matrix contains the given path coefficient.
- **row**: Character. The rownames of the matrix containing each path coefficient; row numbers are used instead if the matrix has no rownames.
- **col**: Character. The colnames of the matrix containing each path coefficient; column numbers are used instead if the matrix has no colnames.
- **Raw.Value**: Numeric values of the raw (i.e., UNstandardized) path coefficients.
- **Raw.SE**: Numeric values of the asymptotic standard errors of the raw path coefficients if SE=TRUE, or NA otherwise.
- **Std.Value**: Numeric values of the standardized path coefficients.
- **Std.SE**: Numeric values of the asymptotic standard errors of the standardized path coefficients if SE=TRUE, or NA otherwise.

If model is a multi-group model containing at least one submodel with RAM expectation, then mxStandardizeRAMpaths() returns a list. The list has a number of elements equal to the number of submodels that either have RAM expectation or contain a submodel that does. List elements corresponding to RAM-expectation submodels contain a dataframe, as described above. List elements corresponding to "container" submodels are themselves lists, of the kind described here.

name="InvSD"),
mxAlgebra( InvSD %*% A %*% solve(InvSD),
name="Az", dimnames=dimnames(factorModel$A)),
mxAlgebra( InvSD %*% S %*% InvSD,
name="Sz", dimnames=dimnames(factorModel$S)),
mxCI(c("Az", "Sz"))
)

## Not run:
factorFit2 <- mxRun(factorModel2, intervals=TRUE)
## Contains point values and confidence limits for all paths:
summary(factorFit2)$CI

## End(Not run)

mxThreshold

Create List of Thresholds

Description
This function creates a list of thresholds which mxModel can use to set up a thresholds matrix for a RAM model.

Usage
mxThreshold(vars, nThresh=NA,
free=FALSE, values=NA, labels=NA,
lbound=NA, ubound=NA)

Arguments
vars character vector. These are the variables for which thresholds are to be specified.
nThresh numeric vector. These are the number of thresholds for each variables listed in 'vars'.
mxThreshold

free  boolean vector. Indicates whether threshold parameters are free or fixed.
values numeric vector. The starting values of the parameters.
labels character vector. The names of the parameters.
lbound numeric vector. The lower bounds of free parameters.
ubound numeric vector. The upper bounds of free parameters.

Details

If you are new to ordinal data modeling and just want something quick to make your ordinal data work, we recommend you try the `umxThresholdMatrix` function in the `umx` package.

The `mxPath` function creates `MxThreshold` objects. These consist of a list of ordinal variables and the thresholds that define the relationship between the observed ordinal variable and the continuous latent variable assumed to underly it. This function directly mirrors the usage of `mxPath`, but is used to specify thresholds rather than means, variances and bivariate relationships.

The ‘vars’ argument specifies which variables you wish to specify thresholds for. Variables are referenced by name, and these names must appear in the ‘manifestVar’ argument of the `mxModel` function if thresholds are to be correctly processed. Additionally, variables for which thresholds are specified must be specified as ordinal factors in whatever data is included in the model.

The ‘nThresh’ argument specifies how many thresholds are to be specified for the variable or variables included in the ‘vars’ argument. The number of thresholds for a particular variable should be one fewer than the number of categories specified for that variable.

The ‘free’ argument specifies whether the thresholds created by the `mxThreshold` function are free or fixed parameters. This argument may take either TRUE for free parameters, FALSE for fixed parameters, or a vector of TRUEs and FALSEs to be applied in order to the created thresholds.

‘values’ is a numeric vector containing the starting values of the created thresholds. This gives a starting point for estimation. The ‘labels’ argument specifies the names of the parameters in the resulting `MxThreshold` object. The ‘lbound’ and ‘ubound’ arguments specify lower and upper bounds for the created threshold parameters.

Thresholds for multiple variables may be specified simultaneously by including a vector of variable names to the ‘vars’ argument. When multiple variables are included in the ‘vars’ argument, the length of the ‘vars’ argument must be evenly divisible by the length of the ‘nThresh’ argument. All subsequent arguments (‘free’ through ‘ubound’) should have their lengths be a factor of the total number of thresholds specified for all variables.

If four variables are included in the ‘vars’ argument, then the ‘nThresh’ argument should contain either one, two or four elements. If the ‘nThresh’ argument specifies two thresholds for each variable, then ‘free’, ‘values’, and all subsequent arguments should specify eight values by including one, two, four or eight elements. Whenever fewer values are specified than are required (e.g., specify two values for eight thresholds), then the entire vector of values is repeated until the required number of values is reached, and will return an error if the correct number of values cannot be achieved by repeating the entire vector.

Value

Returns a list of thresholds.
mxTryHard

References

See Also
umxThresholdMatrix demo("mxThreshold") mxPath for comparable specification of paths. mxMatrix for a matrix-based approach to thresholds specification; mxModel for the container in which mxThresholds are embedded. More information about the OpenMx package may be found here.

Examples
library(OpenMx)
# threshold objects for three variables: 2 binary, and one ordinal.
mxThreshold(vars = c("z1", "z2", "z3"), nThresh = c(1,1,2),
   free = TRUE, values = c(-1, 0, -.5, 1.2) )

mxTryHard

Make multiple attempts to run a model

Description
Makes multiple attempts to fit an MxModel object with mxRun() until the optimizer yields an acceptable solution or the maximum number of attempts is reached. Between attempts, start values are perturbed by random numbers, and optimization-control parameters may be altered. From among its attempts, the function returns the fitted, post-mxRun() model with the smallest fit-function value, and can print to the console the start values it used for that model.

Usage
mxTryHard(model, extraTries = 10, greenOK = FALSE, loc = 1, scale = 0.25,
   initialGradientStepSize = imxAutoOptionValue("Gradient step size"),
   initialGradientIterations = imxAutoOptionValue('Gradient iterations'),
   initialTolerance=as.numeric(mxOption(NULL, 'Optimality tolerance')),
   checkHess = TRUE, fit2beat = Inf, paste = TRUE.iterationSummary=FALSE,
   bestInitsOutput=TRUE, showInits=FALSE, verbose=0, intervals = FALSE,
   finetuneGradient=TRUE, jitterDistrib=c("runif","rnorm","rcauchy"),
   maxMajorIter=3000, OKstatuscodes, wtgcsv=c("prev","best","initial"), silent=FALSE)

mxTryHardOrig(model, finetuneGradient=FALSE, maxMajorIter=NA,
   wtgcsv=c("prev","best"), ...)

mxTryHardctsem(model, initialGradientStepSize = .00001,
   initialGradientIterations = 1,
   initialTolerance=1e-12,jitterDistrib="rnorm", ...)

mxTryHardWideSearch(model, finetuneGradient=FALSE, jitterDistrib="rcauchy",
   exhaustive=TRUE, wtgcsv="prev", ...)
mxTryHardOrdinal(model, greenOK = TRUE, checkHess = FALSE, 
finetuneGradient = FALSE, exhaustive = TRUE, 
OKstatuscodes = c(0, 1, 5, 6), wtgcsv = c("prev", "best"), ...)

Arguments

model: The MxModel to be run.
extraTries: The number of attempts to run the model in addition to the first. In effect, is the maximum number of attempts mxTryHard() will make, since the function will stop once an acceptable solution is reached. Defaults to 10 (for mxTryHard()), in which case a maximum of 11 total attempts will be made.
greenOK: Logical; is a solution with Mx status GREEN (optimizer status code 1) acceptable? Defaults to FALSE (for mxTryHard()). Ignored if a value is provided for OKstatuscodes.
loc, scale: Numeric. The location and scale parameters of the distribution from which random values are drawn to perturb start values between attempts, defaulting respectively to 1 and 0.25. See below, under "Details," for additional information.
initialGradientStepSize, initialGradientIterations, initialTolerance: Numeric. Initial values of optimization-control parameters passed to mxComputeGradientDescent() if model is using the default compute plan.
checkHess: Logical; is a positive-definite Hessian a requirement for an acceptable solution? Defaults to TRUE (for mxTryHard()). If TRUE, the Hessian and standard errors are calculated with each fit attempt, irrespective of the value of relevant options. The exception is if model or any of its submodels contains MxConstraints, in which case checkHess is coerced to FALSE.
fit2beat: Numeric upper limit to the fit function value that an acceptable solution may have. Useful if a nested submodel of model has already been fitted, since model, with its additional free parameters, should not yield a fit function value any greater than that of the submodel.
paste: Logical. If TRUE (default), start values for the returned fitted model are printed to console as a comma-separated string. This is useful if the user wants to copy-paste these values into an R script, say, in an omxSetParameters() statement. If FALSE, the vector of start values is printed as-is. Note that this vector, from omxGetParameters(), has names corresponding to the free parameters; these names are not displayed when paste=TRUE.
iterationSummary: Logical. If TRUE, displays parameter estimates and fit values for every fit attempt. Defaults to FALSE. Value of TRUE is overridden by silent=TRUE.
bestInitsOutput: Logical. If TRUE, displays starting values that resulted in best fit, according to format specified by paste argument. Defaults to TRUE. Value of TRUE is overridden by silent=TRUE.
showInits: Logical. If TRUE, displays starting values for every fit attempt. Defaults to FALSE. Value of TRUE is overridden by silent=TRUE.
If model is using the default compute plan, is passed to \texttt{mxComputeGradientDescent()} to specify level of output printed to console during optimization.

Logical. If \texttt{TRUE}, \texttt{mxTryHard()} will estimate any specified confidence intervals.

Logical. If \texttt{TRUE} (default for \texttt{mxTryHard()}), then as repeated fit attempts appear to be improving, \texttt{mxTryHard()} will adjust optimization-control parameters \texttt{gradientStepSize}, \texttt{gradientIterations}, and \texttt{tolerance}, as well as argument scale, to "fine-tune" its convergence toward an optimal solution. \texttt{finetuneGradient=FALSE} is recommended for analyses involving thresholds.

Character string naming which random-number distribution—either uniform (rectangular), normal (Gaussian), or Cauchy—to be used to perturb start values. Defaults to the uniform distribution (for \texttt{mxTryHard()}). See below, under "Details," for additional information.

Logical. If \texttt{FALSE} (default for \texttt{mxTryHard()}), \texttt{mxTryHard()} stops making additional attempts once it reaches an acceptable solution. If \texttt{TRUE}, the function instead continues until it reaches its maximum number of attempts (as per \texttt{extraTries}), and returns the best solution it found.

Integer; passed to \texttt{mxComputeGradientDescent()} Defaults to 3000, which was the internally hardcoded value \texttt{mxTryHard()} used in at least one prior version of OpenMx. Value of \texttt{NA} is permitted, in which case \texttt{mxTryHard()} will calculate a value via the on-load default formula for the "Major iterations" option.

Optional integer vector containing optimizer status codes that an acceptable solution is permitted to have. \texttt{mxTryHard()} always considers a status code of 0 to be acceptable, this argument notwithstanding. By default, \texttt{mxTryHard()} will consider status code 0 acceptable, and, if \texttt{greenOK=TRUE}, status code 1 as well. If a value is supplied for \texttt{OKstatuscodes} that conflicts with \texttt{greenOK}, \texttt{OKstatuscodes} controls.

Character vector. "Where to get current start values." See below, under "Details," for additional information.

Logical; defaults to \texttt{FALSE}. If \texttt{TRUE}, most message-printing is suppressed, except for those which advise the user of errors, warnings, or a poor solution from the \texttt{MxModel} object to be returned; this overrides \texttt{iterationSummary}, \texttt{bestInitsOutput}, and \texttt{showInits}.

Additional arguments to be passed to \texttt{mxTryHard()}.  

\texttt{mxTryHardOrig()}, \texttt{mxTryHardctsem()}, \texttt{mxTryHardWideSearch()}, and \texttt{mxTryHardOrdinal()} are wrapper functions to the main workhorse function \texttt{mxTryHard()}. Each wrapper function has default values for certain arguments that are tailored toward a specific purpose. \texttt{mxTryHardOrig()} imitates the functionality of the earliest implementations of \texttt{mxTryHard()} in OpenMx's history; its chief purpose is to find good start values that lead to an acceptable solution. \texttt{mxTryHardctsem()} uses \texttt{mxTryHard()} to 'zero in' on an acceptable solution with models that can be difficult to optimize, such as continuous-time state-space models. \texttt{mxTryHardWideSearch()} uses \texttt{mxTryHard()} to search a wide region of the parameter space, in hope of avoiding local fitfunction minima.
mxTryHardOrdinal() attempts to use mxTryHard() as well as it can be used with models involving ordinal data.

Argument wtgcsv dictates where mxTryHard() is permitted to find free-parameter values, at the start of each fit attempt after the first, before randomly perturbing them to create the current fit attempt’s start values. If "prev" is included, then mxTryHard() is permitted to use the parameter estimates of the most recent non-error fit attempt. If "best" is included, then mxTryHard() is permitted to use the parameter estimates at the best solution so far. If "initial" is included, then mxTryHard() is permitted to use the initial start values in model, as provided by the user. The default is to permit all three, in which case mxTryHard() is written to use the best solution’s values if available, and otherwise to use the most recent solution’s values, but to periodically revert to the initial values if recent fit attempts have not improved on the best solution.

Once the start values are located for the current fit attempt, they are randomly perturbed before being assigned to the MxModel. The distributional family from which the perturbations are randomly generated is dictated by argument jitterDistrib. The distribution is parametrized by arguments loc and scale, respectively the location and scale parameters. The location parameter is the distribution’s median. For the uniform distribution, scale is the absolute difference between its median and extrema (i.e., half the width of the rectangle); for the normal distribution, scale is its standard deviation; and for the Cauchy, scale is one-half its interquartile range. Start values are first multiplied by random draws from a distribution with the provided loc and scale, then added to random draws from a distribution with the same scale but with a median of zero.

Value

Usually, mxTryHard() returns a post-mxRun() MxModel object. Specifically, this will be the fitted model having the smallest fit-function value found by mxTryHard() during its attempts. The start values used to obtain this fitted model are printed to console if bestInitsOutput=TRUE.

If every attempt at running model fails, mxTryHard() returns an object of class 'try-error'.

mxTryHard() throws a warning if the returned MxModel object has a nonzero status code (unless nonzero status codes are considered acceptable per argument greenOK or OKstatuscodes).

Examples

library(OpenMx)

data(demoOneFactor) # load the demoOneFactor dataframe

manifests <- names(demoOneFactor) # set the manifest to the 5 demo variables

latents <- c("G") # define 1 latent variable

model <- mxModel(model="One Factor", type="RAM",

manifestVars = manifests,

latentVars = latents,

mxPath(from=latents, to=manifests, labels=paste("b", 1:5, sep="")),

mxPath(from=manifests, arrows=2, labels=paste("u", 1:5, sep="")),

mxPath(from=latents, arrows=2, free=FALSE, values=1.0),
```r
mxData(cov(demoOneFactor), type="cov", numObs=500)
model <- mxTryHard(model) # Run the model, returning the result into model
summary(model) # Show summary of the fitted model
```

---

### mxTypes

**List Currently Available Model Types**

**Description**

This function returns a vector of the currently available type names.

**Usage**

```r
mxTypes()
```

**Value**

Returns a character vector of type names.

**Examples**

```r
mxTypes()
```

---

### mxVersion

**Returns Current Version String**

**Description**

This function returns a string with the current version number of OpenMx. Optionally (with `verbose = TRUE` (the default)), it prints a message containing the version of R, the platform, and the optimiser.

**Usage**

```r
mxVersion(model = NULL, verbose = TRUE)
```

**Arguments**

- `model` : optional `MxModel` to request optimizer from (default = `NULL`)
- `verbose` : Whether to print version information to the console (default = `TRUE`)

**References**

The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.
Examples

# Print useful version information.
x = mxVersion()

# If you just want the version, use this call.
x = mxVersion(verbos=false)

library(OpenMx)
data(demoOneFactor)  # load the demoOneFactor dataframe
manifests <- names(demoOneFactor)  # set the manifest to the 5 demo variables
latents <- c("G")  # define 1 latent variable
model <- mxModel(model = "One Factor", type = "RAM",
                 manifestVars = manifests,
                 latentVars = latents,
                 mxPath(from = latents, to = manifests, labels = paste("b", 1:5, sep = "")),
                 mxPath(from = manifests, arrows = 2, labels = paste("u", 1:5, sep = "")),
                 mxPath(from = latents, arrows = 2, free = FALSE, values = 1.0),
                 mxData(cov(demoOneFactor), type = "cov", numObs = 500)
)
mxVersion(model, verbose = TRUE)

myAutoregressiveData

Example data with autoregressively related columns

Data set used in some of OpenMx’s examples.

Usage

data("myAutoregressiveData")

Format

A data frame with 100 observations on the following variables.

- x1 x variable and time 1
- x2 x variable and time 2
- x3 x variable and time 3
- x4 x variable and time 4
- x5 x variable and time 5
myFADataRaw

Details
The rows are independently and identically distributed, but the columns are and auto-correlation structure.

Source
Simulated.

References
The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.

Examples

```r
data(myAutoregressiveData)
round(cor(myAutoregressiveData), 2)
# note the sub-diagonal correlations (lag 1)
# x1-x2, x2-x3, x3-x4, x4-x5
# and the second sub-diagonal correlations (lag 2)
# x1-x3, x2-x4, x3-x5
```

---

myFADataRaw  
*Example 500-row dataset with 12 generated variables*

Description
Twelve columns of generated numeric data: x1 x2 x3 x4 x5 x6 y1 y2 y3 z1 z2 z3.

Usage
data(myFADataRaw)

Details
The x variables intercorrelate around .6 with each other.
The y variables intercorrelate around .5 with each other, and correlate around .3 with the X vars.
There are three ordinal variables, z1, z2, and z3.
The data are used in some OpenMx examples, especially confirmatory factor analysis.
There are no missing data.

Examples

```r
data(myFADataRaw)
str(myFADataRaw)
```
myGrowthKnownClassData

Data for a growth mixture model with the true class membership

Description

Data set used in some of OpenMx’s examples.

Usage

data("myGrowthKnownClassData")

Format

A data frame with 500 observations on the following variables.

- x1: x variable and time 1
- x2: x variable and time 2
- x3: x variable and time 3
- x4: x variable and time 4
- x5: x variable and time 5
- c: Known class membership variable

Details

The same as myGrowthMixtureData, but with the class membership variable.

Source

Simulated.

References

The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.

Examples

data(myGrowthKnownClassData)

# plot the observed trajectories
# blue lines are class 1, green lines are class 2
colSel <- c('blue', 'green')[myGrowthKnownClassData$c]
matplot(t(myGrowthKnownClassData[,-6]), type='l', lty=1, col=colSel)
myGrowthMixtureData

Data for a growth mixture model

Description
Data set used in some of OpenMx’s examples.

Usage

data("myGrowthMixtureData")

Format
A data frame with 500 observations on the following variables.

x1  x variable and time 1
x2  x variable and time 2
x3  x variable and time 3
x4  x variable and time 4
x5  x variable and time 5

Details
The same as myGrowthKnownClassData, but without the class membership variable.

Source
Simulated.

References
The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.

Examples

data(myGrowthMixtureData)

matplot(t(myGrowthMixtureData), type='l', lty=1)

data(myGrowthKnownClassData)
all(myGrowthKnownClassData[,,-6]==myGrowthMixtureData)
myLongitudinalData  
*Data for a linear latent growth curve model*

**Description**

Data set used in some of OpenMx’s examples.

**Usage**

```r
data("myLongitudinalData")
```

**Format**

A data frame with 500 observations on the following variables.

- `x1` x variable and time 1
- `x2` x variable and time 2
- `x3` x variable and time 3
- `x4` x variable and time 4
- `x5` x variable and time 5

**Details**

Linear growth model with mean intercept around 10, and slope of about 1.5.

**Source**

Simulated.

**References**

The OpenMx User’s guide can be found at [http://openmx.ssri.psu.edu/documentation](http://openmx.ssri.psu.edu/documentation).

**Examples**

```r
data(myLongitudinalData)
matplot(t(myLongitudinalData), type='l', lty=1)
```
**myRegData**

Example regression data with correlated predictors

**Description**
Data set used in some of OpenMx’s examples.

**Usage**
```
data("myRegData")
```

**Format**
A data frame with 100 observations on the following variables.

- **w**  Predictor variable
- **x**  Predictor variable
- **y**  Predictor variable
- **z**  Outcome variable

**Details**
w, x, and y are predictors of z. x and y are correlated.

**Source**
Simulated.

**References**
The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.

**Examples**
```
data(myRegData)
summary(lm(z ~ ., data=myRegData))
```
### myRegDataRaw

| myRegDataRaw | Example regression data with correlated predictors |

#### Description

Data set used in some of OpenMx’s examples.

#### Usage

```r
data("myRegDataRaw")
```

#### Format

A data frame with 100 observations on the following variables.

- **w**  Predictor variable
- **x**  Predictor variable
- **y**  Predictor variable
- **z**  Outcome variable

#### Details

w, x, and y are predictors of z. x and y are correlated. Equal to `myRegData`.

#### Source

Simulated.

myTwinData

myTwinData  Twin data on weight and height

Description

Data set used in some of OpenMx’s examples.

Usage

data("myTwinData")

Format

A data frame with 3808 observations on the following variables.

fam  Family ID variable
age  Age of the twin pair. Range: 17 to 88.
zyg  Integer codes for zygosity and gender combinations
part
wt1  Weight in kilograms for twin 1
wt2  Weight in kilograms for twin 2
ht1  Height in meters for twin 1
ht2  Height in meters for twin 2
htwt1 Product of ht and wt for twin 1
htwt2 Product of ht and wt for twin 2
bmi1  Body Mass Index for twin 1
bmi2  Body Mass Index for twin 2

Details

Height and weight are highly correlated, and each individually highly heritable. These data present and opportunity for multivariate behavior genetics modeling.

Named-entity

A named entity is an S4 object that can be referenced by name.

Details

Every named entity is guaranteed to have a slot called "name". Within a model, the named entities of that model can be accessed using the $ operator. Access is limited to one nesting depth, such that if 'B' is a submodel of 'A', and 'C' is a matrix of 'B', then 'C' must be accessed using A$B$C.

The following S4 classes are named entities in the OpenMx library: MxAlgebra, MxConstraint, MxMatrix, MxModel, MxData, and MxObjective.

Examples

```r
library(OpenMx)

# Create a model, add a matrix to it, and then access the matrix by name.

testModel <- mxModel(model="anEmptyModel")

testMatrix <- mxMatrix(type="Full", nrow=2, ncol=2, values=c(1,2,3,4), name="yourMatrix")

yourModel <- mxModel(testModel, testMatrix, name="noLongerEmpty")

yourModel$yourMatrix
```

```

nuclear_twin_design_data

Twin data from a nuclear family design

Description

Data set used in some of OpenMx's examples.

Usage

data("nuclear_twin_design_data")
```
Format
A data frame with 1743 observations on the following variables.
Twin1
Twin2
Father
Mother
zyg Zygosity of the twin pair

Details
This is a wide format data set. A single variable has values for different member of the same nuclear family.

Source
Likely simulated.

**Usage**

```r
data("numHess2")
```

**Format**

A 12 by 12 data frame containing Hessian matrix (numeric variables a-l)

**Examples**

```r
data(numHess2)
str(numHess2)
```

---

**omxAllInt**

*All Interval Multivariate Normal Integration*

---

**Description**

omxAllInt computes the probabilities of a large number of cells of a multivariate normal distribution that has been sliced by a varying number of thresholds in each dimension. While the same functionality can be achieved by repeated calls to omxMnor, omxAllInt is more efficient for repeated operations on a single covariance matrix. omxAllInt returns an nx1 matrix of probabilities cycling from lowest to highest thresholds in each column with the rightmost variable in covariance changing most rapidly.

**Usage**

```r
omxAllInt(covariance, means, ...)
```

**Arguments**

- **covariance** the covariance matrix describing the multivariate normal distribution.
- **means** a row vector containing means of the variables of the underlying distribution.
- **...** a matrix or set of matrices containing one column of thresholds for each column of covariance. Each column must contain a strictly increasing set of thresholds for the corresponding variable of the underlying distribution. NA values in these thresholds indicate that the list of thresholds in that column has ended.
Details

covariance and means contain the covariances and means of the multivariate distribution from which probabilities are to be calculated.

covariance must be a square covariance or correlation matrix with one row and column for each variable.

means must be a vector of length nrows(covariance) that contains the mean for each corresponding variable.

All further arguments are considered threshold matrices.

Threshold matrices contain locations of the hyperplanes delineating the intervals to be calculated. The first column of the first matrix corresponds to the thresholds for the first variable represented by the covariance matrix. Subsequent columns of the same matrix correspond to thresholds for subsequent variables in the covariance matrix. If more variables exist in the covariance matrix than in the first threshold matrix, the first column of the second threshold matrix will be used, and so on. That is, if covariance is a 4x4 matrix, and the three threshold matrices are specified, one with a single column and the others with two columns each, the first column of the first matrix will contain thresholds for the first variable in covariance, the two columns of the second matrix will correspond to the second and third variables of covariance, respectively, and the first column of the third threshold matrix will correspond to the fourth variable. Any extra columns will be ignored.

Each column in the threshold matrices must contain some number of strictly increasing thresholds, delineating the boundaries of a cell of integration. That is, if the integral from -1 to 0 and 0 to 1 are required for a given variable, the corresponding threshold column should contain the values -1, 0, and 1, in that order. Thresholds may be set to Inf or -Inf if a boundary at positive or negative infinity is desired.

Within a threshold column, a value of +Inf, if it exists, is assumed to be the largest threshold, and any rows after it are ignored in that column. A value of NA, if it exists, indicates that there are no further thresholds in that column, and is otherwise ignored. A threshold column consisting of only +Inf or NA values will cause an error.

For all i>1, the value in row i must be strictly larger than the value in row i-1 in the same column.

The return value of omxAllInt is a matrix consisting of a single column with one row for each combination of threshold levels.

Examples

data(myFADataRaw)

covariance <- cov(myFADataRaw[,1:5])
means <- colMeans(myFADataRaw[,1:5])

# Integrate from -Infinity to 0 and 0 to 1 on first variable
thresholdForColumn1 <- cbind(c(-Inf, 0, 1))
# Note: The first variable will never be calculated from 1 to +Infinity.
# These columns will be integrated from -Inf to -1, -1 to 0, etc.
thresholdsForColumn2 <- cbind(c(-Inf, -1, 0, 1, Inf))
thresholdsForColumns3and4 <- cbind(c(-Inf, 1.96, 2.326, Inf),
                                   c(-Inf, -1.96, 2.326, Inf))

# The integration
omxAllInt(covariance, means,
           thresholdForColumn1, thresholdsForColumn2,
           thresholdsForColumns3and4, thresholdsForColumn2)
# Notice that columns 2 and 5 are assigned identical thresholds.

# An alternative specification of the same calculation follows
covariance <- cov(myFADataram[,1:5])
means <- colMeans(myFADataram[,1:5])

# Note NAs to indicate the end of the sequence of thresholds.
thresholds <- cbind(c(-Inf, 0, 1, NA, NA),
                     c(-Inf, -1, 0, 1, Inf),
                     c(-Inf, 1.96, 2.32, Inf, NA),
                     c(-Inf, -1.96, 2.32, Inf, NA),
                     c(-Inf, -1, 0, 1, Inf))

omxAllInt(covariance, means, thresholds)

---

**omxApply**

*On-Demand Parallel Apply*

**Description**

If the snowfall library is loaded, then this function calls `sfApply`. Otherwise it invokes `apply`.

**Usage**

`omxApply(x, margin, fun, ...)`

**Arguments**

- `x`: a vector (atomic or list) or an expressions vector. Other objects (including classed objects) will be coerced by `as.list`.
- `margin`: a vector giving the subscripts which the function will be applied over.
- `fun`: the function giving the subscripts which the function will be applied over.
- `...`: optional arguments to `fun`.

**See Also**

`omxLapply`, `omxSapply`
Examples

```r
x <- cbind(x1 = 3, x2 = c(4:1, 2:5))
dimnames(x)[[1]] <- letters[1:8]
omxApply(x, 2, mean, trim = .2)
```

**omxAssignFirstParameters**

*Assign First Available Values to Model Parameters*

**Description**

Sometimes you may have a free parameter with two different starting values in your model. OpenMx will not run a model until all instances of a free parameter have the same starting value. It is often sufficient to arbitrarily select one of those starting values for optimization.

This function accomplishes that task of assigning valid starting values to the free parameters of a model. It selects an arbitrary current value (the "first" value it finds, where "first" is not defined) for each free parameter and uses that value for all instances of that parameter in the model.

**Usage**

```r
omxAssignFirstParameters(model, indep = FALSE)
```

**Arguments**

- `model` a MxModel object.
- `indep` assign parameters to independent submodels.

**See Also**

`omxGetParameters, omxSetParameters`

**Examples**

```r
A <- mxMatrix('Full', 3, 3, values = c(1:9), labels = c('a', 'b', NA),
               free = TRUE, name = 'A')
model <- mxModel(model=A, name = 'model')
model <- omxAssignFirstParameters(model)

# Note: All cells with the same label now have the same start value.
# Note also that NAs are untouched.

model$matrices$A

# $labels
#     [,1] [,2] [,3]
#  [1,]  1  4  2
#  [2,]  3  5  3
#  [3,]  5  6  4
```
omxBrownie

Description

This function returns a brownie recipe.

Usage

omxBrownie(quantity=1, walnuts=TRUE)

Arguments

quantity Number of batches of brownies desired. Defaults to one.
walnuts Logical. Indicates whether walnuts are to be included in the brownies. Defaults to TRUE.

Details

Returns a brownie recipe. Alter the 'quantity' variable to make more pans of brownies. Ingredients, equipment and procedure are listed, but neither ingredients nor equipment are provided.

Value

Returns a brownie recipe.

References

The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.

Examples

# Return a brownie recipe
omxBrownie()
omxCheckCloseEnough  Approximate Equality Testing Function

Description
This function tests whether two numeric vectors or matrixes are approximately equal to one another, within a specified threshold.

Usage
omxCheckCloseEnough(a, b, epsilon = 10^(-15), na.action = na.fail)

Arguments
- **a**: a numeric vector or matrix
- **b**: a numeric vector or matrix
- **epsilon**: a non-negative tolerance threshold
- **na.action**: either na.fail (default) or na.pass. Use of na.omit or na.exclude is not recommended.

Details
Arguments ‘a’ and ‘b’ must be of the same type, i.e., they must be either vectors of equal dimension or matrices of equal dimension. The two arguments are compared element-wise for approximate equality. If the absolute value of the difference of any two values is greater than the threshold, then an error will be thrown. If ‘a’ and ‘b’ are approximately equal to each other, by default the function will print a statement informing the user the test has passed. To turn off these print statements use options(“mxPrintUnitTests” = FALSE).

When na.action is set to na.pass, a and b are expected to have identical missingness patterns.

- omxCheckCloseEnough(matrix(3, 3), matrix(4, 3, 3), epsilon = 2)
  # Throws an error
- try(omxCheckCloseEnough(c(1, 2, 3), c(1.1, 1.9, 3.0), epsilon = 0.01))
omxCheckEquals

Equality Testing Function

Description

This function tests whether two objects are equal using the ‘==’ operator.

Usage

omxCheckEquals(a, b)

Arguments

a  the first value to compare.
b  the second value to compare.

Details

Performs the ‘==’ comparison on the two arguments. If the two arguments are not equal, then an error will be thrown. If ‘a’ and ‘b’ are equal to each other, by default the function will print a statement informing the user the test has passed. To turn off these print statements use options("mxPrintUnitTests" = FALSE).

# Throws an error
try(omxCheckEquals(c(1, 2, 3), c(2, 1, 3)))
omxCheckError  Correct Error Message Function

Description

This function tests whether the correct error message is thrown.

Usage

omxCheckError(expression, message)

Arguments

expression  an R expression that produces an error
message     a character string with the desired error message

Details

Arguments ‘expression’ and ‘message’ give the expression that generates the error and the message that is supposed to be generated, respectively.

References

The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.

Examples

A <- mxMatrix('Full', 1, 1, labels = 'data.foo', free = TRUE, name = 'A')
model <- mxModel('model', A)
omxCheckError(mxRun(model),
paste("The definition variable 'data.foo'",
"has been assigned to a",
"free parameter in matrix 'A'"))
omxCheckCloseEnough(matrix(3, 3, 3), matrix(4, 3, 3), epsilon = 2)
# Throws error, check the message
tmsg <- paste("In omxCheckCloseEnough(c(1, 2, 3), c(1.1, 1.9, 3), 0.01)",
": not equal to within 0.01 : '1 2 3' and '1.1 1.9 3'")
omxCheckError(omxCheckCloseEnough(c(1, 2, 3), c(1.1, 1.9, 3.0), .01), tmsg)
omxCheckIdentical  

Exact Equality Testing Function

Description

This function tests whether two objects are equal.

Usage

omxCheckIdentical(a, b)

Arguments

a  
the first value to compare.

b  
the second value to compare.

Details

Performs the ‘identical’ comparison on the two arguments. If the two arguments are not equal, then an error will be thrown. If ‘a’ and ‘b’ are equal to each other, by default the function will print a statement informing the user the test has passed. To turn off these print statements use options("mxPrintUnitTests" = FALSE).

References

See Also

omxCheckCloseEnough, omxCheckWithinPercentError, omxCheckSetEquals, omxCheckTrue, omxCheckEquals

Examples

omxCheckIdentical(c(1, 2, 3), c(1, 2, 3))

omxCheckIdentical(FALSE, FALSE)

# Throws an error
try(omxCheckIdentical(c(1, 2, 3), c(2, 1, 3)))
omxCheckNamespace

Description
This is an internal function exported for those people who know what they are doing.

Usage
omxCheckNamespace(model, namespace)

Arguments
model
namespace

Details
This function checks that the named entities in the model are valid.

omxCheckSetEquals
Set Equality Testing Function

Description
This function tests whether two vectors contain the same elements.

Usage
omxCheckSetEquals(a, b)

Arguments
a
b
the first vector to compare.
the second vector to compare.

Details
Performs the ‘setequal’ function on the two arguments. If the two arguments do not contain the same elements, then an error will be thrown. If ‘a’ and ‘b’ contain the same elements, by default the function will print a statement informing the user the test has passed. To turn off these print statements use options("mxPrintUnitTests" = FALSE).

# Throws an error
try(omxCheckSetEquals(c(1, 2, 3, 4), c(2, 1, 3)))

omxCheckTrue  Boolean Equality Testing Function

Description

This function tests whether an object is equal to TRUE.

Usage

omxCheckTrue(a)

Arguments

a  the value to test.

Details

Checks element-wise whether an object is equal to TRUE. If any of the elements are false, then an error will be thrown. If ‘a’ is TRUE, by default the function will print a statement informing the user the test has passed. To turn off these print statements use options("mxPrintUnitTests" = FALSE).

# Throws an error
try(omxCheckTrue(FALSE))

==

omxCheckWarning  Correct Warning Message Function

Description

This function tests whether the correct warning message is thrown.

Usage

omxCheckWarning(expression, message)

Arguments

expression an R expression that produces a warning
message a character string with the desired warning message

Details

Arguments ‘expression’ and ‘message’ give the expression that generates the warning and the message that is supposed to be generated, respectively.

foo <- omxCheckWarning(mxFIMLObjective('cov', 'mean'), msg)
omxCheckWithinPercentError

Approximate Percent Equality Testing Function

Description

This function tests whether two numeric vectors or matrixes are approximately equal to one another, within a specified percentage.

Usage

omxCheckWithinPercentError(a, b, percent = 0.1)

Arguments

- `a` a numeric vector or matrix.
- `b` a numeric vector or matrix.
- `percent` a non-negative percentage.

Details

Arguments ‘a’ and ‘b’ must be of the same type, ie. they must be either vectors of equal dimension or matrices of equal dimension. The two arguments are compared element-wise for approximate equality. If the absolute value of the difference of any two values is greater than the percentage difference of ‘a’, then an error will be thrown. If ‘a’ and ‘b’ are approximately equal to each other, by default the function will print a statement informing the user the test has passed. To turn off these print statements use options("mxPrintUnitTests" = FALSE).

omxCheckWithinPercentError(c(1, 2, 3), c(1.1, 1.9, 3.0), percent = 50)
omxCheckWithinPercentError(matrix(3, 3, 3), matrix(4, 3, 3), percent = 150)

# Throws an error
try(omxCheckWithinPercentError(c(1, 2, 3), c(1.1, 1.9, 3.0), percent = 0.01))
omxConstrainMLThresholds

Description
Add constraint to ML model to keep thresholds in order

Usage
omxConstrainMLThresholds(model, dist = 0.1)

Arguments
- model: the MxModel to which constraints should be added
- dist: unused

Details
This function adds a nonlinear constraint to an ML model. The constraint keeps the thresholds in order. Constraints often slow model estimation, however, keeping the thresholds in increasing order helps ensure the likelihood function is well-defined. If you’re having problems with ordinal data, this is one of the things to try.

Value
a new MxModel object with the constraints added

See Also
demo("omxConstrainMLThresholds")

omxDefaultComputePlan

Description
This function generates a default compute plan, where "default compute plan" refers to an object of class MxComputeSequence which is appropriate for use in a wide variety of cases. The exact specification of the plan will depend upon the arguments provided to omxDefaultComputePlan().

Usage
omxDefaultComputePlan(modelName=NULL, intervals=FALSE, useOptimizer=TRUE, optionList=options()$mxOption)
omxDetectCores

Arguments

modelName  Optional (defaults to NULL) character string, providing the name of the MxModel the fitfunction of which is to be evaluated, and usually, optimized.

intervals  Logical; will confidence intervals be computed? Defaults to FALSE.

useOptimizer  Logical; will a fitfunction be minimized? Defaults to TRUE.

optionList  List of mxOptions. Defaults to the current list of global mxOptions.

Details

At minimum, argument optionList must include “Gradient algorithm”, “Gradient iterations”, “Gradient step size”, “Calculate Hessian”, and “Standard Errors”. Users are advised to set “Calculate Hessian” and “Standard Errors” to ”No” if the compute plan is to be used in an MxModel containing MxConstraints.

Value

Returns an object of class MxComputeSequence.

Examples

foo <- omxDefaultComputePlan(modelName="bar")
str(foo)

omxDetectCores  omxDetectCores

Description

Detects the number of cores on the local machine

Usage

omxDetectCores(...)
omxGetBootstrapReplications

omxGetBootstrapReplications

**Description**
Checks a variety of conditions to ensure that bootstrap replications are available and valid. Throws exception if things go wrong. Otherwise, replications are returned to the caller.

**Usage**
- `omxGetBootstrapReplications(model)`
- `omxBootstrapCov(model)`

**Arguments**
- `model` an MxModel object

**Value**
a matrix or covariance matrix of bootstrap parameter estimates

---

omxGetNPSOL

omxGetNPSOL

**Description**
Get the non-CRAN version of OpenMx from the OpenMx website.

**Usage**
- `omxGetNPSOL()`

**Details**
This function

**Value**
Invisible NULL

**Examples**
```r
## Not run: omxGetNPSOL()
```
omxGetParameters

Fetch Model Parameters

Description

Return a vector of the chosen parameters from the model.

Usage

omxGetParameters(model, indep = FALSE, free = c(TRUE, FALSE, NA),
fetch = c('values', 'free', 'lbound', 'ubound', 'all'))

Arguments

model a MxModel object
indep fetch parameters from independent submodels.
free fetch either free parameters (TRUE), or fixed parameters or both types. Default value is TRUE.
fetch which attribute of the parameters to fetch. Default choice is ‘values’.

Details

The argument ‘free’ dictates whether to return only free parameters or only fixed parameters or both free and fixed parameters. The function can return unlabelled free parameters (parameters with a label of NA). These anonymous free parameters will be identified as ‘modelname.matrixname[row.col]’. It will not return fixed parameters that have a label of NA. No distinction is made between ordinary labels, definition variables, and square bracket constraints. The function will return either a vector of parameter values, or free/fixed designations, or lower bounds, or upper bounds, depending on the ‘fetch’ argument. Using fetch with ‘all’ returns a data frame that is populated with all of the attributes.

See Also

omxSetParameters, omxLocateParameters, omxAssignFirstParameters

Examples

library(OpenMx)

A <- mxMatrix('Full', 2, 2, labels = c("A11", "A12", "A21", NA), values= 1:4,
free = c(TRUE,TRUE,FALSE,TRUE), byrow=TRUE, name = 'A')
model <- mxModel(A, name = 'model')

# Request all free parameters in model
omxGetParameters(model)

# A11  A12 model.A[2,2]
# Request fixed parameters from model
omxGetParameters(model, free = FALSE)
# A21
# 3

A$labels
# [,1] [,2]
# [1,] "A11" "A12"
# [2,] "A21" NA

A$free
# [,1] [,2]
# [1,] TRUE TRUE
# [2,] FALSE TRUE

# Example using un-labelled parameters

# Read in some demo data
data(demoOneFactor)
# Grab the names for manifestVars
manifestVars <- names(demoOneFactor)
nVar = length(manifestVars) # 5 variables
factorModel <- mxModel("One Factor",
  mxMatrix(name="A", type="Full", nrow=nVar, ncol=1, values=0.2, free=TRUE, lbound = 0.0, labels=letters[1:nVar]),
  mxMatrix(name="L", type="Symm", nrow=1, ncol=1, values=1, free=FALSE),
  # the "U" matrix has nVar (5) anonymous free parameters
  mxMatrix(name="U", type="Diag", nrow=nVar, ncol=nVar, values=1, free=TRUE),
  mxAlgebra(expression=A %&% L + U, name="R"),
  mxExpectationNormal(covariance="R", dimnames=manifestVars),
  mxFitFunctionML(),
  mxData(observed=cov(demoOneFactor), type="cov", numObs=500)
)

# Get all free parameters
params <- omxGetParameters(factorModel)
labound <- omxGetParameters(factorModel, fetch="lbound")

# Set new values for these params, saving them in a new model
newFactorModel <- omxSetParameters(factorModel, names(params), values = 1:10)
# Read out the values from the new model
newParams <- omxGetParameters(newFactorModel)
**omxGraphviz**

**Description**

Get the potency of a matrix for inversion speed-up

**Usage**

```
omxGetRAMDepth(A, maxdepth = nrow(A) - 1)
```

**Arguments**

- `A` MxMatrix object
- `maxdepth` Numeric. maximum depth to check

**Details**

This function is used internally by the `mxExpectationRAM` function to determine how far to expand

\[
(I - A)^{-1} = I + A + A^2 + A^3 + \ldots.
\]

It is similarly used by `mxExpectationLISREL` in expanding

\[
(I - B)^{-1} = I + B + B^2 + B^3 + \ldots.
\]

In many situations \(A^2\) is a zero matrix (nilpotent of order 2). So when \(A\) has large dimension it is much faster to compute \(I + A\) than \((I - A)^{-1}\).

---

**omxGraphviz**

*Show RAM Model in Graphviz Format*

**Description**

The function accepts a RAM style model and outputs a visual representation of the model in Graphviz format. The function will output either to a file or to the console. The recommended file extension for an output file is ".dot".

**Usage**

```
omxGraphviz(model, dotFilename = "")
```

**Arguments**

- `model` An RAM-type model.
- `dotFilename` The name of the output file. Use "" to write to console.

**Value**

Invisibly returns a string containing the model description in graphviz format.

**References**

The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation.
omxHasDefaultComputePlan

Description
Determine whether the model has a default complete plan (i.e., not custom).

Usage
omxHasDefaultComputePlan(model)

Arguments
model

omxLapply

On-Demand Parallel Lapply

Description
If the snowfall library is loaded, then this function calls sfLapply. Otherwise it invokes lapply.

Usage
omxLapply(x, fun, ...)

Arguments
x
fun
...

See Also
omxApply, omxSapply

Examples
x <- list(a = 1:10, beta = exp(-3:3), logic = c(TRUE,FALSE,FALSE,TRUE))
# compute the list mean for each list element
omxLapply(x, mean)
omxLocateParameters

Summarize Model Parameters

Description

Return a data.frame object summarizing the free parameters in the model.

Usage

omxLocateParameters(model, labels = NULL, indep = FALSE)

Arguments

model a MxModel object
labels optionally specify which free parameters to retrieve.
indep fetch parameters from independent submodels.

Details

Invoking the function with the default value for the ‘labels’ argument retrieves all the free parameters. The ‘labels’ argument can be used to select a subset of the free parameters. Note that ‘NA’ is a valid possible input to the ‘labels’ argument.

See Also

omxGetParameters, omxSetParameters, omxAssignFirstParameters

Examples

A <- mxMatrix('Full', 2, 2, labels = c("A11", "A12", NA, NA), values= 1:4,
               free = TRUE, byrow = TRUE, name = 'A')

model <- mxModel(A, name = 'model')

# Request all free parameters in model
omxLocateParameters(model)

# Request free parameters "A11" and all NAs
omxLocateParameters(model, c("A11", NA))
**omxLogical**

Logical `mxAlgebra()` operators

### Description

`omxNot` computes the unary negation of the values of a matrix. `omxAnd` computes the binary and of two matrices. `omxOr` computes the binary or of two matrices. `omxGreaterThan` computes a binary greater than of two matrices. `omxLessThan` computes the binary less than of two matrices. `omxApproxEquals` computes a binary equals within a specified epsilon of two matrices.

### Usage

```r
omxNot(x)
omxAnd(x, y)
omxOr(x, y)
omxGreaterThan(x, y)
omxLessThan(x, y)
omxApproxEquals(x, y, epsilon)
```

### Arguments

- **x**
  - the first argument, the matrix which the logical operation will be applied to.
- **y**
  - the second argument, applicable to binary functions.
- **epsilon**
  - the third argument, specifies the error threshold for `omxApproxEquals`. \(\text{Abs}(x[i][j]-y[i][j])\) must be less than \(\text{epsilon}[i][j]\).

### Examples

```r
A <- mxMatrix(values = runif(25), nrow = 5, ncol = 5, name = 'VarA')
B <- mxMatrix(values = runif(25), nrow = 5, ncol = 5, name = 'VarB')
EPSILON <- mxMatrix(values = 0.04*1:25, nrow = 5, ncol = 5, name = "EPSILON")

model <- mxModel(A, B, EPSILON, name = 'model')

mxEval(omxNot(A), model)
mxEval(omxGreaterThan(A, B), model)
mxEval(omxLessThan(B, A), model)
mxEval(omxOr(omxNot(A), B), model)
mxEval(omxAnd(omxNot(B), A), model)
mxEval(omxApproxEquals(A, B, EPSILON), model)
```
omxManifestModelByParameterJacobian

Estimate the Jacobian of manifest model with respect to parameters

Description

The manifest model excludes any latent variables or processes. For RAM and LISREL models, the manifest model contains only the manifest variables with free means, covariance, and thresholds.

Usage

omxManifestModelByParameterJacobian(model, defvar.row = 1, standardize = FALSE)

Arguments

model an mxModel
defvar.row which row to use for definition variablesstandardize logical, whether or not to standardize the parameters

Details

The Jacobian is estimated by the central finite difference.

If the standardize argument is TRUE, then the Jacobian is for the standardized model. For Normal expectations the standardized manifest model has the covariances returned as correlations, the variances returned as ones, the means returned as zeros, and the thresholds are returned as z-scores. For the thresholds the z-scores are computed by using the model-implied means and variances.

Value

a matrix with manifests in the rows and original parameters in the columns

See Also

mxGetExpected
### omxMatrixOperations  
*MxMatrix operations*

**Description**

*omxCbind* columnwise binding of two or more *MxMatrices*. *omxRbind* rowwise binding of two or more *MxMatrices*. *omxTranspose* transpose of *MxMatrix*.

**Usage**

```r
omxCbind(..., allowUnlabeled =
    getOption("mxOptions")[["Allow Unlabeled"]],
    dimnames = NA, name = NA)

omxRbind(..., allowUnlabeled =
    getOption("mxOptions")[["Allow Unlabeled"]],
    dimnames = NA, name = NA)

omxTranspose(matrix, allowUnlabeled =
    getOption("mxOptions")[["Allow Unlabeled"]],
    dimnames = NA, name = NA)
```

**Arguments**

- `...`: two or more *MxMatrix* objects
- `matrix`: *MxMatrix* input
- `allowUnlabeled`: whether or not to accept free parameters with NA labels
- `dimnames`: list. The dimnames attribute for the matrix: a list of length 2 giving the row and column names respectively. An empty list is treated as NULL, and a list of length one as row names. The list can be named, and the list names will be used as names for the dimensions.
- `name`: an optional character string indicating the name of the *MxMatrix* object

### omxMnor  
**Multivariate Normal Integration**

**Description**

Given a covariance matrix, a means vector, and vectors of lower and upper bounds, returns the multivariate normal integral across the space between bounds.

**Usage**

```r
omxMnor(covariance, means, lbound, ubound)
```
Arguments

- **covariance**: the covariance matrix describing the multivariate normal distribution.
- **means**: a row vector containing means of the variables of the underlying distribution.
- **lbound**: a row vector containing the lower bounds of the integration in each variable.
- **ubound**: a row vector containing the upper bounds of the integration in each variable.

Details

The order of columns in the ‘means’, ‘lbound’, and ‘ubound’ vectors are assumed to be the same as that of the covariance matrix. That is, means[i] is considered to be the mean of the variable whose variance is in covariance[i,i]. That variable will be integrated from lbound[i] to ubound[i] as part of the integration.

The value of ubound[i] or lbound[i] may be set to Inf or -Inf if a boundary at positive or negative infinity is desired.

For all i, ubound[i] must be strictly greater than lbound[i].

Examples

```r
data(myFADataRaw)
covariance <- cov(myFADataRaw[,1:3])
means <- colMeans(myFADataRaw[,1:3])
lbound <- c(-Inf, 0, 1) # Integrate from -Infinity to 0 on first variable
ubound <- c(0, Inf, 2.5) # From 0 to +Infinity on second, and from 1 to 2.5 on third
omxMnor(covariance, means, lbound, ubound)
# 0.0005995
```

```
# An alternative specification of the bounds follows
# Integrate from -Infinity to 0 on first variable
v1bound = c(-Inf, 0)
# From 0 to +Infinity on second
v2bound = c(0, Inf)
# and from 1 to 2.5 on third
v3bound = c(1, 2.5)
bounds <- cbind(v1bound, v2bound, v3bound)
lbound <- bounds[1,]
ubound <- bounds[2,]
omxMnor(covariance, means, lbound, ubound)
```
omxParallelCI

Dedicated functions for calculating confidence intervals without redoing the primary optimization.

Description

omxParallelCI() calculates confidence intervals for an already-run MxModel object that contains an MxInterval object (i.e., an mxCI() statement), without recalculating point estimates, fit-function derivatives, or expectations. The "parallel" in the function’s name refers to the not-yet-implemented feature of running independent submodels in parallel. omxRunCI() is a wrapper for omxParallelCI() with arguments run=TRUE and independentSubmodels=FALSE, and is the recommended interface.

Usage

omxParallelCI(model, run = TRUE, verbose=0L, independentSubmodels=TRUE)

omxRunCI(model, verbose=0L)

Arguments

model An MxModel object that contains an MxInterval object (i.e., an mxCI() statement).
run Logical; should the resulting MxModel object be passed through mxRun() before being returned? Defaults to TRUE (for omxParallelCI()).
verbose Integer; defaults to zero; verbosity level passed to MxCompute* objects.
independentSubmodels Logical; defaults to TRUE (for omxParallelCI()). See below under "Details."
omxParallelCI

Details

When `independentSubmodels=TRUE`, `omxParallelCI()` creates an independent MxModel object for each quantity specified in the ‘reference’ slot of model’s MxInterval object, and places these independent MxModels inside `model`. Each of these independent submodels calculates the confidence limits of its own quantity when the container model is run. When `independentSubmodels=FALSE`, no submodels are added to `model`. Instead, `model` is provided with a dedicated compute plan consisting only of an MxComputeConfidenceInterval step. Note that using `independentSubmodels=FALSE` will overwrite any compute plan already inside `model`.

Value

The functions return `model`, augmented with independent submodels (if `independentSubmodels=TRUE`) or with a non-default compute plan (if `independentSubmodels=FALSE`), and possibly having been passed through `mxRun()` (if `run=TRUE`). Naturally, if `run=FALSE`, the user can subsequently run the returned model to obtain confidence intervals. Users are cautioned that the returned model may not be very amenable to being further modified and re-fitted (e.g., having some free parameters fixed via `omxSetParameters()` and passed through `mxRun()` to get new point estimates) unless the added submodels or the non-default compute plan are eliminated. The exception is if `run=TRUE` and `independentSubmodels=TRUE` (which is always the case with `omxRunCI()`), since the non-default compute plan is set to be non-persistent, and will automatically be replaced with a default compute plan the next time the model is passed to `mxRun()`.

Examples

```r
require(OpenMx)
data(demoOneFactor)
manifests <- names(demoOneFactor)
lats <- c("G")
factorModel <- mxModel("One Factor",
  type="RAM",
  manifestVars=manifests,
  latentVars=lats,
  mxPath(from=lats, to=manifests),
  mxPath(from=manifests, arrows=2),
  mxPath(from=lats, arrows=2, free=FALSE, values=1.0),
  mxData(observed=cov(demoOneFactor), type="cov",
  numObs=500),
# add confidence intervals for free params in A and S matrices
  mxCI(c('A', 'S')))
factorRun <- mxRun(factorModel)
factorCI <- omxParallelCI(factorRun)
factorCI2 <- omxRunCI(factorRun)
```
omxQuotes

Description
Quote helper function, often for error messages.

Usage
omxQuotes(name)

Arguments
name: a character vector

Details
This is a helper function for creating a nicely put together formatted string.

Value
a character string

Examples
omxQuotes(c("Oh", "blah", "dee", "Oh", "blah", "da"))
omxQuotes(c("A", "S", "F"))
omxQuotes("Hello World")

omxRAMtoML

Description
Convert a RAM model to an ML model

Usage
omxRAMtoML(model)

Arguments
model: the MxModel

Details
This is a legacy function that was once used to convert RAM models to ML models in the old (1.0 release of OpenMx) objective function style.
omxRMSEA

Value
an ML model with an ML objective

Get the RMSEA with confidence intervals from model

Description
This function calculates the Root Mean Square Error of the Approximation (RMSEA) for a model and computes confidence intervals for that fit statistic.

Usage
omxRMSEA(model, lower=.025, upper=.975, null=.05, ...)

Arguments
model An MxModel object for which the RMSEA is desired
lower The lower confidence bound for the confidence interval
upper The upper confidence bound for the confidence interval
null Value of RMSEA used to test for close fit
... Further named arguments passed to summary

Details
To help users obtain fit statistics related to the RMSEA, this function confidence intervals and a test for close fit. The user determines how close the fit is required to be by setting the null argument to the value desired for comparison.

Value
A named vector with elements lower, est.rmsea, upper, null, and ‘Prob(x <= null)’.

References

Examples
require(OpenMx)
data(demoOneFactor)
manifests <- names(demoOneFactor)
latents <- c("G")
factorModel <- mxModel("One Factor",
  type="RAM",
  manifestVars=manifests,
latentVars=latents,
mxPath(from=latents, to=manifests),
mxPath(from=manifests, arrows=2),
mxPath(from=latents, arrows=2, free=FALSE, values=1.0),
mxData( observed= cov(demoOneFactor), type="cov", numObs=500))

factorRun <- mxRun(factorModel)
factorSat <- mxRefModels(factorRun, run=TRUE)
summary(factorRun, refModels=factorSat)
# Gives RMSEA with 95% confidence interval

omxRMSEA(factorRun, .05, .95, refModels=factorSat)
# Gives RMSEA with 90% confidence interval
# and probability of 'close enough' fit

omxSapply

---

**omxSapply**

*On-Demand Parallel Sapply*

---

### Description

If the snowfall library is loaded, then this function calls `sfSapply`. Otherwise it invokes `sapply`.

### Usage

```r
omxSapply(x, fun, ..., simplify = TRUE, USE.NAMES = TRUE)
```

### Arguments

- **x**: a vector (atomic or list) or an expressions vector. Other objects (including classed objects) will be coerced by `as.list`.
- **fun**: the function to be applied to each element of `x`.
- **...**: optional arguments to `fun`.
- **simplify**: logical; should the result be simplified to a vector or matrix if possible?
- **USE.NAMES**: logical; if `TRUE` and if `x` is a character, use `x` as `names` for the result unless it had names already.

### See Also

- `omxApply`, `omxLapply`

### Examples

```r
x <- list(a = 1:10, beta = exp(-3:3), logic = c(TRUE, FALSE, FALSE, TRUE))
# compute the list mean for each list element
omxSapply(x, quantile)
```
Create Reference (Saturated and Independence) Models

Description

This function creates and, optionally, runs saturated and independence (null) models of a base model or data set for use with mxSummary to enable fit indices that depend on these models.

Usage

mxRefModels(x, run=FALSE)

Arguments

x A MxModel object, data frame, or matrix.
run logical. If TRUE, runs the models before returning; otherwise returns built models without running.

Details

For typical structural equation models the saturated model is the free-est possible model. Not only all variances (and, when possible, all means) are estimated, but also all covariances. In the case of ordinal data, the ordinal means are fixed to zero and the thresholds are estimated. For binary variables, those variances are also constrained to one. This is the free-est possible model that is identified. The saturated model is used in calculating fit statistics such as the RMSEA, and Chi-squared fit indices.

The independence model, sometimes called the null model, is a model in which each variable is treated as being completely independent of every other variable. As such, all the variances and, when possible, all means are estimated. However, covariances are set to zero. Ordinal variables are handled the same for the independence and saturated models. The independence model is used, along with the saturated model, to create CFI and TLI fit indices.

The saturated and independence models could be used to create further fit indices. However, OpenMx does not recommend using GFI, AGFI, NFI (aka Bentler-Bonett), or SRMR. The page for mxSummary has information about why.

When the mxFitFunctionMultigroup fit function is used, mxRefModels creates the appropriate multi-group saturated and independence models. Saturated and independence models are created separately for each group. Each group has its own saturated and independence model. The multigroup saturated model is a multi-group model where each group has its own saturated model, and similarly for the independence model.

One potentially important limitation of the mxRefModels function is for behavior-genetic models. If variables ‘x’, ‘y’, and ‘z’ are measured on twins 1 and 2 creating the modeled variables ‘x1’, ‘y1’, ‘z1’, ‘x2’, ‘y2’, ‘z2’, then this function may not create the intended saturated or independence models. In particular, the means of ‘x1’ and ‘x2’ are estimated separately. Similarly, the covariance of ‘x1’ with ‘y1’ and ‘x2’ with ‘y2’ are allowed be be distinct: \( \text{cov}(x1, y1) \neq \text{cov}(x2, y2) \). Moreover, the cross-twin covariances are estimated: e.g. \( \text{cov}(x1, y2) = 0 \).
Another potential misuse of this function is for models with definition variables. If definition variables are used, the saturated and independence model may not be correct because they do not account for the definition variables.

When an MxModel has been run, some effort is made to make the reference models for only the variables used in the model. For covariance data, all variables are modeled by default. For raw data when the model has been run, only the modeled variables are used in the reference models. This matches the behavior of `mxModel`.

In general, it is best practice to give `mxRefModels` a model that has already been run.

There are a few considerations specific to IFA models (`mxExpectationBA81`). The independence model preserves equality constraints among item parameters from the original model. The saturated model is a multinomial distribution with the proportions equal to the proportions in your data. For example, if you have 2 dichotomous items then there are 4 possible response patterns: 00, 01, 10, 11. A multinomial distribution for these 2 items is fully specified by 3 proportions or 3 parameters: \( a, b, c \cdot 1 - (a + b + c) \). Hence, there is no need to optimize the saturated model. When there is no missing data, the deviance is immediately known as \( -2 \cdot \sum (\log \text{proportions}) \).

Typical Bayesian priors involve latent factors (various densities on the pseudo-guessing lower bound, log norm on loading, and uniqueness prior). These priors cannot be included in the independence model because there are no latent factors. Therefore, exercise caution when comparing the independence model to a model that includes Bayesian priors.

`mxRefModels()` is not compatible with GREML expectation, as there is no sensible general definition for a saturated GREML-type model.

**Examples**

```r
require(OpenMx)
data(demoOneFactor)
manifests <- names(demoOneFactor)
latents <- c("G")
factorModel <- mxModel("OneFactor", type = "RAM",
  manifestVars = manifests, latentVars = latents,
  mxPath(from = latents, to=manifests, values = diag(var(demoOneFactor))*.2),
  mxPath(from = manifests, arrows = 2, values = diag(var(demoOneFactor))*.8),
  mxPath(from = latents, arrows = 2, free = FALSE, values = 1),
  mxData(cov(demoOneFactor), type = "cov", numObs = 500)
)
factorRun <- mxRun(factorModel)
factorSat <- mxRefModels(factorRun, run=TRUE)
summary(factorRun)
summary(factorRun, refModels=factorSat)

# A raw-data example where using mxRefModels adds fit indices
## Not run:
ml <- mxModel("OneFactor", type = "RAM",
  manifestVars = manifests, latentVars = latents,
  mxPath(latents, to=manifests, values = diag(var(demoOneFactor))*.2),
  mxPath(latents, arrows = 2, values = diag(var(demoOneFactor))*.8),
  mxPath(from = latents, arrows = 2, free = FALSE, values = 1),
  mxData(cov(demoOneFactor), type = "cov", numObs = 500)
)
mlRun <- mxRun(ml)
mlSat <- mxRefModels(mlRun, run=TRUE)
summary(mlRun)
summary(mlRun, refModels=mlSat)
```
omxSelectRowsAndCols

Filter rows and columns from an mxMatrix

Description

This function filters rows and columns from a matrix using a single row or column R matrix as a selector.

Usage

omxSelectRowsAndCols(x, selector)
omxSelectRows(x, selector)
omxSelectCols(x, selector)

Arguments

x the matrix to be filtered
selector A single row or single column R matrix indicating which values should be filtered from the mxMatrix.

Details

omxSelectRowsAndCols, omxSelectRows, and omxSelectCols returns the filtered entries in a target matrix specified by a single row or single column selector matrix. Each entry in the selector matrix is treated as a logical data indicating if the corresponding entry in the target matrix should be excluded (0 or FALSE) or included (not 0 or TRUE). Typically the function is used to filter data from a target matrix using an existence vector which specifies what data entries are missing. This can be seen in the demo: RowObjectiveFIMLBivariateSaturated.

Value

Returns a new matrix with the filtered data.
References

The function is most often used when filtering data for missingness. This can be seen in the demo: RowObjectiveFIML.BivariateSaturated. The OpenMx User’s guide can be found at http://openmx.ssri.psu.edu/documentation. The `omxSelect*` functions share some similarity to the Extract function in the R programming language.

Examples

```r
loadings <- c(1, -0.625, 0.1953125, 1, -0.375, 0.0703125, 1, -0.375, 0.0703125)
loadings <- matrix(loadings, 3, 3, byrow= TRUE)
existenceList <- c(1, 0, 1)
existenceList <- matrix(existenceList, 1, 3, byrow= TRUE)
rowsAndCols <- omxSelectRowsAndCols(loadings, existenceList)
rows <- omxSelectRows(loadings, existenceList)
cols <- omxSelectCols(loadings, existenceList)
```

---

**omxSetParameters** Assign Model Parameters

Description

Modify the attributes of parameters in a model. This function cannot modify parameters that have NA labels. Often you will want to call `omxAssignFirstParameters` after using this, to force the starting values of equated parameters to the same value (otherwise the model cannot begin to be evaluated).

Usage

```r
omxSetParameters(model, labels, free = NULL, values = NULL,
                  newlabels = NULL, lbound = NULL, ubound = NULL, indep = FALSE,
                  strict = TRUE, name = NULL)
```

Arguments

- **model**: an MxModel object.
- **labels**: a character vector of target parameter names.
- **free**: a boolean vector of parameter free/fixed designations.
- **values**: a numeric vector of parameter values.
- **newlabels**: a character vector of new parameter names.
- **lbound**: a numeric vector of lower bound values.
- **ubound**: a numeric vector of upper bound values.
- **indep**: boolean. set parameters in independent submodels.
- **strict**: boolean. If TRUE then throw an error when a label does not appear in the model.
- **name**: character string. (optional) a new name for the model.

Examples

A <- mxMatrix('Full', 3, 3, labels = c('a', 'b', NA), free = TRUE, name = 'A')
model <- mxModel(model = "testModel", A, name = 'model')

# set value of cells labelled "a" and "b" to 1 and 2 respectively
model <- omxSetParameters(model, c('a', 'b'), values = c(1, 2))

# set label of cell labelled "a" to "b" and vice versa
model <- omxSetParameters(model, c('a', 'b'), newlabels = c('b', 'a'))

# set label of cells labelled "a" to "b"
model <- omxSetParameters(model, c('a'), newlabels = 'b')

# ensure initial values are the same for each instance of a labeled parameter
model <- omxAssignFirstParameters(model)

omxSymbolTable  Internal OpenMx algebra operations

Description

This is an internal table used in the OpenMx backend.

OpenMx  OpenMx: An package for Structural Equation Modeling and Matrix Algebra Optimization

Description

OpenMx is a package for structural equation modeling, matrix algebra optimization and other statistical estimation problems. Try the example below. We try and have useful help files: for instance help(mxRun) to learn more. Also the reference manual

Details

OpenMx solves algebra optimization and statistical estimation problems using matrix algebra. Most users use it for Structural equation modeling.

The core function is mxModel, which makes a model. Models are containers for data, matrices, mxPaths algebras, bounds and constraints. Models most often have an expectation function (e.g., mxExpectationNormal) to calculate the expectations for the model. Models need a fit function.
Several of these are built-in (e.g., \texttt{mxFitFunctionML}) OpenMx also allows user-defined fit functions for purposes not covered by the built-in functions. (e.g., \texttt{mxFitFunctionR} or \texttt{mxFitFunctionAlgebra}).

Once built, the resulting \texttt{mxModel} can be run (i.e., optimized) using \texttt{mxRun}. This returns the fitted model.

You can see the resulting parameter estimates, algebra evaluation etc using \texttt{summary(yourModel)}

The user’s manual is online (see reference below), but functions \texttt{mxRun, mxModel, mxMatrix} all have working examples to get you started as well.

The main OpenMx functions are: \texttt{mxAlgebra, mxBounds, mxCI, mxConstraint, mxData, mxMatrix, mxModel, and mxPath}

Expectation functions include \texttt{mxExpectationNormal, mxExpectationRAM, mxExpectationLISREL,} and \texttt{mxExpectationStateSpace;}

Fit functions include \texttt{mxFitFunctionML, mxFitFunctionAlgebra, mxFitFunctionRow and mxFitFunctionR.}

OpenMx comes with several useful datasets built-in. Access them using \texttt{data(package="OpenMx")}

**ordinalTwinData**  
*Data for ordinal twin model*

**Description**

Example data for ordinal twin-data modelling. Three variables measured in each twin.

**Usage**

```r
data("ordinalTwinData")
```

**Format**

A data frame with 139 observations on the following 7 variables.

- **zyg** a numeric vector
- **var1_twin1** a numeric vector
- **var2_twin1** a numeric vector
- **var3_twin1** a numeric vector
- **var1_twin2** a numeric vector
- **var2_twin2** a numeric vector
- **var3_twin2** a numeric vector

**Examples**

```r
data(ordinalTwinData)
str(ordinalTwinData)
```
rvectorize  Vectorize By Row

Description
This function returns the vectorization of an input matrix in a row by row traversal of the matrix. The output is returned as a column vector.

Usage
rvectorize(x)

Arguments
x an input matrix.

See Also
cvectorize, vech, vechs

Examples
rvectorize(matrix(1:9, 3, 3))
rvectorize(matrix(1:12, 3, 4))

summary.MxModel  Model Summary

Description
This function returns summary statistics of a model. These include model statistics (parameters, degrees of freedom and likelihood), fit statistics such as AIC, parameter estimates and standard errors (when available), as well as version and timing information and possible warnings about estimates.

Usage
## S3 method for class 'MxModel'
summary(object, ..., verbose=FALSE)
Arguments

object A MxModel object.

... Any number of named arguments (see below).

verbose Whether to include extra diagnostic information.

Details

mxSummary allows the user to set or override the following parameters of the model:

numObs Numeric. Specify the total number of observations for the model.

numStats Numeric. Specify the total number of observed statistics for the model.

refModels List of MxModel objects. Specify a saturated and independence likelihoods in single argument for testing.

SaturatedLikelihood Numeric or MxModel object. Specify a saturated likelihood for testing.

SaturatedDoF Numeric. Specify the degrees of freedom of the saturated likelihood for testing.

IndependenceLikelihood Numeric or MxModel object. Specify an independence likelihood for testing.

IndependenceDoF Numeric. Specify the degrees of freedom of the independence likelihood for testing.

indep Logical. Set to FALSE to ignore independent submodels in summary.

verbose logical. Changes the printing style for summary (see Details)

boot.quantile numeric. A vector of quantiles to be used to summarize bootstrap replication.

boot.SummaryType character. One of ‘quantile’ or ‘bcbci’.

Standard Output

The standard output consists of a table of free parameters, tables of model and fit statistics, information on the time taken to run the model, the optimizer used, and the version of OpenMx.

Table of free parameters

Free parameters in the model are reported in a table with columns for the name (label) of the parameter, the matrix, row and col containing the parameter, the parameter estimate itself, and any lower or upper bounds set for the parameter.

note: An exclamation mark (“!”) printed after a bound in the lbound or ubound columns indicates that the solution was sufficiently close to the bound that the optimizer could not ignore the bound during its last few iterations.

Additional columns: standard errors and ’A’ (asymmetry) warning column

When the information matrix is available, either approximated by the Hessian or from bootstrap resampling, standard errors are reported in the column “Std.Error”. If the information matrix was estimated using finite differences then an additional diagnostic column ’A’ is displayed. An exclamation point in the ’A’ column indicates that the gradient appears to be asymmetric and the standard error may not accurately reflect the variability of that parameter. As a precaution, it is recommended that you compare the SEs with likelihood-based or bootstrap confidence intervals.
Fit statistics

AIC and BIC Information Criteria are reported in a table showing different versions of the information criteria obtained using different penalties. AIC is reported with both a Parameters Penalty and a Degrees of Freedom Penalty version. AIC generally takes the form $Fit + 2 \times k$. With the Parameters Penalty version, $k$ is the number of free parameters: $AIC_{param} = Fit + 2 \times param$. With the Degrees of Freedom Penalty, $k$ is minus one times the model degrees of freedom. So the penalty is subtracted instead of added: $AIC_{param} = Fit - 2 \times df$. The Degrees of Freedom penalty was used in Classic Mx. BIC is defined similarly: $Fit + k \times log(N)$ where $k$ is either the number of free parameters or minus one times the model degrees of freedom. The Sample-Size Adjusted BIC is only defined for the parameters penalty: $Fit + k \times log((N + 2)/24)$. For raw data models, $Fit$ is the minus 2 log likelihood, $-2LL$. For covariance data, $Fit$ is the Chi-squared statistic. The $-2LL$ and saturated likelihood values reported under covariance data are not necessarily meaningful on their own, but their difference yields the Chi-squared value.

Additional fit statistics

When the model has a saturated likelihood, several additional fit indices are printed, including Chi-Squared, CFI, TLI, RMSEA and $p$ RMSEA $\leq 0.05$. For covariance data, saturated and independence models are fitted automatically so all fit indices are reported.

For raw data (to save computational time), the reference models needed to compute these absolute statistics are not estimated by default. They are available once you fit reference models.

The refModels, SaturatedLikelihood, SaturatedDoF, IndependenceLikelihood, and IndependenceDoF arguments can be used to obtain these additional fit statistics. An easy way to make reference models for most cases is provided by the mxRefModels function (see the example given in mxRefModels).

When the SaturatedLikelihood or IndependenceLikelihood arguments are used, OpenMx attempts to calculate the appropriate degrees of freedom. However, depending on the model, it may sometimes be necessary for the user to also explicitly provide the corresponding SaturatedDoF and/or IndependenceDoF. Again, for the vast majority of cases, the mxRefModels function handles these situations effectively and conveniently.

Notes on fit statistics

With regard to RMSEA, it is important to note that OpenMx does not currently make a multigroup adjustment that some other structural equation modeling programs make. In particular, we do not multiply the single-group RMSEA by the square root of the number of groups as suggested by Steiger (1998). The RMSEA we use is based on the model likelihood (and degrees of freedom) as compared to the saturated model likelihood (and degrees of freedom), and we do not feel the adjustment is appropriate in this case.

OpenMx does not recommend (and does not compute) some fit indices including GFI, AGFI, NFI, and SRMR. The Goodness of Fit Index (GFI) and Adjusted Goodness of Fit Index (AGFI) are not recommended because they are strongly influenced by sample size and have rather high Type I error rates (Sharma, Mukherjee, Kumar, & Dillon, 2005). The Normed Fit Index (NFI) has no penalty for model complexity. That is, adding more parameters to a model always improves the NFI, regardless of how useful those parameters are. Because the Non-Normed Fit Index (NNFI), also known as the Tucker-Lewis Index (TLI), does adjust for model complexity it is used instead. Lastly, the Standardized Root Mean Square Residual (SRMR) is not reported because it (1) only applies to covariance models, having no direct extension to missing data, (2) has no penalty for model complexity, similar to the NFI, and (3) is positively biased (Hu & Bentler, 1999).
The `verbose` argument changes the printing style for the summary of a model. When `verbose=FALSE`, a relatively minimal amount of information is printed: the free parameters, the likelihood, and a few fit indices. When `verbose=TRUE`, the compute plan, data summary, and additional timing information are always printed. Moreover, available fit indices are printed regardless of whether or not they are defined. The undefined fit indices are printed as NA. In addition, the condition number of the information matrix, and the maximum absolute gradient may also be shown.

**note:** The `verbose` argument only changes the printing style, all of the same information is calculated and exists in the output of `summary`. More information is displayed when `verbose=TRUE`, and less when `verbose=FALSE`.

**Summary for bootstrap replications**

Summarization of bootstrap replications is controlled by two options: ‘`boot.quantile`’ and ‘`boot.SummaryType`’. To obtain a two-sided 95% width confidence interval, use `boot.quantile=c(.025,.975)`. Options for ‘`boot.SummaryType`’ are ‘quantile’ (using R’s standard `stats::quantile` function) and ‘`bcbci`’ for bias-corrected bootstrap confidence intervals. The latter, ‘`bcbci`’, is the default due to its superior theoretical properties. However, its bias-correction can lead to nonsensical results if the number of bootstrap replications is too small for the desired coverage probability. For example, a lower confidence limit of -Inf, or an upper confidence limit smaller than the point estimate, are signals that more replications are needed.

**tr**

**trace**

**Description**

This function returns the trace of an n-by-n square matrix x, defined to be the sum of the elements on the main diagonal (the diagonal from the upper left to the lower right).

**Usage**

```r
t(x)
```

**Arguments**

- `x` an input matrix. Must be square

**Details**

The input matrix must be square.

**See Also**

`vech`, `rvectorize`, `cvectorize`
**Examples**

```r
tr(matrix(1:9, 3, 3))
tr(matrix(1:12, 3, 4))
```

**Description**

Australian twin data with 3,808 observations on the 12 variables including body mass index (BMI) assessed in both MZ and DZ twins.

Questionnaires were mailed to 5,967 pairs age 18 years and over. These data consist of completed questionnaires returned by both members of 3,808 (64 percent) pairs. There are two cohort blocks in the data: a younger group (zyg 1:5), and an older group (zyg 6:10).

It is a wide dataset, with two individuals per line. Families are identified by the variable “fam”.

Data include zygosity (zyg), along with heights in metres, weights in kg, and the derived variables BMI in kg/m^2 (stored as “htwt1” and “htwt2”), as well as the 7 times the natural log of this variable, stored as bmi1 and bmi2. The logged values are more closely normally distributed while scaling by 7 places them into a similar range to the original variable.

For convenience, zyg is broken out into separate “zygosity” and “cohort” factors. “zygosity” is coded as a factor with 5-levels: MZFF, MZMM, DZFF, DZMM, DZOS. DZOS are in Female/Male wide order.

**Usage**

```r
data(twinData)
```

**Format**

A data frame with 3808 observations on the following 12 variables.

- **fam** The family ID
- **age** Age in years (of both twins)
- **zyg** Code for zygosity and cohort (see details)
- **part** A numeric vector
- **wt1** Weight of twin 1 (kg)
- **wt2** Weight of twin 2 (kg)
- **ht1** Height of twin 1 (m)
- **ht2** Height of twin 2 (m)
- **htwt1** Raw BMI of twin 1 (kg/m^2)
twinData

htwt2  Raw BMI of twin 2 (kg/m^2)
bmi1  7*log(BMI) of twin 1
bmi2  7*log(BMI) of twin 2
cohort Either “younger” or “older”
zygosity Zygosity factor with levels: MZFF, MZMM, DZFF, DZMM, DZOS
age1  Age of Twin 1
age2  Age of Twin 2

Details

“zyg” codes twin-zygosity as follows: 1 == MZFF (i.e MZ females) 2 == MZMM (i.e MZ males)
3 == DZFF 4 == DZMM 5 == DZOS opposite sex pairs

Note: zyg 6:10 are for an older cohort in the sample. So: 6 == MZFF (i.e MZ females) 7 == MZMM
(i.e MZ males) 8 == DZFF 9 == DZMM 10 == DZOS opposite sex pairs

The “zygosity” and “cohort” variables take care of this for you (conventions differ).

References

Examples

data(twinData)
str(twinData)
plot(wt1 ~ wt2, data = twinData)
selVars = c("bmi1", "bmi2")
mzData <- subset(twinData, zyg == 1, selVars)
dzData <- subset(twinData, zyg == 3, selVars)

# equivalently
mzData <- subset(twinData, zygosity == "MZFF", selVars)

# Disregard sex, pick older cohort
mz <- subset(twinData, zygosity %in% c("MZFF","MZMM") & cohort == "older", selVars)
twin_NA_dot

Twin data on weight and height

Description

Data set used in some of OpenMx’s examples.

Usage

data("twin_NA_dot")

Format

A data frame with 3808 observations on the following variables.

- **fam**: Family ID variable
- **age**: Age of the twin pair. Range: 17 to 88.
- **zyg**: Integer codes for zygosity and gender combinations
- **part**: Part
- **wt1**: Weight in kilograms for twin 1
- **wt2**: Weight in kilograms for twin 2
- **ht1**: Height in meters for twin 1
- **ht2**: Height in meters for twin 2
- **htwt1**: Product of ht and wt for twin 1
- **htwt2**: Product of ht and wt for twin 2
- **bmi1**: Body Mass Index for twin 1
- **bmi2**: Body Mass Index for twin 2

Details

Same as myTwinData but has . as the missing data value instead of NA.

Examples

data(twin_NA_dot)
summary(twin_NA_dot)
# Note that all variables are treated as factors because of the missing data coding.
vec2diag  
*Create Diagonal Matrix From Vector*

**Description**

Given an input row or column vector, `vec2diag` returns a diagonal matrix with the input argument along the diagonal.

**Usage**

```
vec2diag(x)
```

**Arguments**

- `x`  
an row or column vector.

**Details**

Similar to the function `diag`, except that the input argument is always treated as a vector of elements to place along the diagonal.

**See Also**

`diag2vec`

**Examples**

```
vec2diag(matrix(1:4, 1, 4))
vec2diag(matrix(1:4, 4, 1))
```

vech  
*Half-vectorization*

**Description**

This function returns the half-vectorization of an input matrix as a column vector.

**Usage**

```
vech(x)
```

**Arguments**

- `x`  
an input matrix.
Details

The half-vectorization of an input matrix consists of the elements in the lower triangle of the matrix, including the elements along the diagonal of the matrix, as a column vector. The column vector is created by traversing the matrix in column-major order.

See Also

vech2full, vechs, rvectorize, cvectorize

Examples

vech(matrix(1:9, 3, 3))
vech(matrix(1:12, 3, 4))

vech2full

Inverse Half-vectorization

Description

This function returns the symmetric matrix constructed from a half-vectorization.

Usage

vech2full(x)

Arguments

x an input single column or single row matrix.

Details

The half-vectorization of an input matrix consists of the elements in the lower triangle of the matrix, including the elements along the diagonal of the matrix, as a column vector. The column vector is created by traversing the matrix in column-major order. The inverse half-vectorization takes a vector and reconstructs a symmetric matrix such that vech2full(vech(x)) is identical to x if x is symmetric.

Note that very few vectors have the correct number of elements to construct a symmetric matrix. For example, vectors with 1, 3, 6, 10, and 15 elements can be used to make a symmetric matrix, but none of the other numbers between 1 and 15 can. An error is thrown if the number of elements in x cannot be used to make a symmetric matrix.

See Also

vechs2full, vech, vechs, rvectorize, cvectorize
Examples

vech2full(1:10)

matrix(1:16, 4, 4)
vech(matrix(1:16, 4, 4))
vech2full(vech(matrix(1:16, 4, 4)))

vechs

Strict Half-vectorization

Description

This function returns the strict half-vectorization of an input matrix as a column vector.

Usage

vechs(x)

Arguments

x an input matrix.

Details

The half-vectorization of an input matrix consists of the elements in the lower triangle of the matrix, excluding the elements along the diagonal of the matrix, as a column vector. The column vector is created by traversing the matrix in column-major order.

See Also

vech, rvectorize, cvectorize

Examples

vechs(matrix(1:9, 3, 3))
vechs(matrix(1:12, 3, 4))
vechs2full  Inverse Strict Half-vectorization

Description
This function returns the symmetric matrix constructed from a strict half-vectorization.

Usage
vechs2full(x)

Arguments
x an input single column or single row matrix.

Details
The strict half-vectorization of an input matrix consists of the elements in the lower triangle of the matrix, excluding the elements along the diagonal of the matrix, as a column vector. The column vector is created by traversing the matrix in column-major order. The inverse strict half-vectorization takes a vector and reconstructs a symmetric matrix such that vechs2full(vechs(x)) is equal to x with zero along the diagonal if x is symmetric.

Note that very few vectors have the correct number of elements to construct a symmetric matrix. For example, vectors with 1, 3, 6, 10, and 15 elements can be used to make a symmetric matrix, but none of the other numbers between 1 and 15 can. An error is thrown if the number of elements in x cannot be used to make a symmetric matrix.
